## Abstract

We present the results of mapping and single-point spectral scans toward Orion-KL/OMC-1 performed as science demonstrations of a 2 mm superconductor-insulator-superconductor receiver, named the Band 4 Receiver (B4R), installed on the Large Millimeter Telescope (LMT), with a diameter of 50 m. To prove the capabilities of mapping and spectral scans with the B4R on the LMT, commissioning observations were conducted employing the On-The-Fly mapping technique toward Orion-KL/OMC-1, which covers a map size of  $5' \times 5'$ . These mapping observations were performed with two frequency settings providing 10 GHz in total (131.4–133.9 GHz and 145.1–147.6 GHz, 136.2–138.7 GHz and 149.9–152.4 GHz) with a frequency resolution of 76.293 kHz. In this study, we conducted spectral line identification analysis for the hot core and compact ridge regions in the Orion-KL with a beam size of  $11''$ – $12''$ . We detected nearly 400 emission lines and identified two recombination lines and 29 molecular species, including isotopologues, deuterated molecules, and vibrational excited states, despite the short integration time. These results of line detection are consistent with those of previous studies. The 29 molecular species include nitrogen (N)-bearing complex organic molecules (COMs) and oxygen (O)-bearing COMs. To demonstrate the capability of the B4R in astrochemistry, we conducted detailed analyses of column densities, rotational temperatures, and relative abundances with respect to  $\text{H}_2$  on two representative COMs, N-bearing  $\text{C}_2\text{H}_5\text{CN}$  and O-bearing  $\text{CH}_3\text{OCHO}$  in the central  $40'' \times 40''$  area of the map. The wide bandwidth of 10 GHz enabled the use of 8 and 34 emission lines, respectively. The spatial differences in the physical and chemical properties between the above two molecules were derived at a spatial resolution of  $\sim 12''$ . The B4R on the LMT was successfully demonstrated to be powerful for mapping and spectral scans and to have high potential for the

study of interstellar chemistry.

**Keywords:** astrochemistry — instrumentation: detectors — ISM: abundances — submillimeter: ISM

## 1 Introduction

A 2 mm band receiver plays an important role not only in determining the redshift ( $z$ ) of dusty star-forming galaxies (DSFGs) or submillimeter galaxies (SMGs) through synergy with a 3 mm band receiver (e.g., Bakx & Dannerbauer 2022) but also in astrochemistry. The interstellar medium or circumstellar shells host more than 300 molecular species<sup>1</sup>, including complex organic molecules (COMs), which are defined as carbon-containing species composed of six or more atoms (Herbst & van Dishoeck 2009). The 2 mm band, which covers molecular species of deuterated molecules (e.g.,  $\text{DCO}^+$ ,  $\text{N}_2\text{D}^+$ ,  $\text{DCN}$ , and  $\text{DNC}$ )<sup>2</sup> and many COMs, is a critical frequency band in astrochemistry (e.g., Ziurys & McGonagle 1993; Martin et al. 2006; Belloche et al. 2014).

The Band 4 Receiver (B4R), a 2 mm band superconductor-insulator-superconductor (SIS) receiver, was installed onto the Large Millimeter Telescope (LMT)-50 m situated at the summit of the Sierra Negra Mountain in Mexico at an altitude of 4600 m. We conducted the On-The-Fly (OTF) mapping observations toward the Orion Kleinmann-Low (Orion-KL) region (Kleinmann & Low 1967) at a distance of  $418 \pm 6$  pc (Kim et al. 2008) in the Orion molecular cloud-1 (OMC-1) to test the observational capabilities of the B4R on the LMT (Kawabe et al. 2024). We obtained demonstration maps with a spatial resolution of  $\sim 11''$ , covering an area of  $10' \times 10'$  in 2018, and  $5' \times 5'$  and  $1.5' \times 1.5'$  in 2019 (Kawabe et al. 2024; Taniguchi et al. 2024). The capability for the OTF mapping using the B4R on the LMT was successfully demonstrated, and high-quality maps covering large regions of major molecular lines (e.g., CS and  $\text{H}_2\text{CO}$ ) were obtained (Kawabe et al. 2024). Moreover, the B4R is capable of spectral scan observations over a wide frequency range, which makes it valuable and highly competitive in advancing molecular identification efforts and essential for understanding chemical reactions and enrichments. The spatial variation in the chemical and physical properties of COMs (e.g., column densities and rotational temperatures) is key to understanding interstellar chemistry and its variety. The Orion-KL region, which is rich in COMs, is one of the most suitable targets for testing the observational capabilities of the B4R on the LMT, such as spectral scans over the 2 mm band and physical and chemical analysis/studies based on mapping spectral scan data.

The Orion-KL region stands as a nearby high-mass star-forming region (HMSFR), harboring protostars, a compact H II region associated with Source I, infrared sources N and Becklin-Nuegebauer (BN) (Becklin & Neugebauer 1967), and dense cores known as the hot core (HC) and compact ridge (CR). The HC region is located close to the southeast of Source I and is presumed to be externally heated by Source I (Zapata et al. 2011). The CR region is located at a separate distance southwest of Source I. The existence of  $\text{H}_2\text{O}$  masers and  $\text{HCOOH}$  in the CR implies the presence of regions of interaction between the Orion-KL outflow and surrounding quiescent gas clouds (e.g., Genzel et al. 1981; Gaume et al. 1998; Liu et al. 2002). The Orion-KL region exhibits distinct chemical properties across its various sub-regions.

The spatial differences between nitrogen (N)-bearing and oxygen (O)-bearing COMs in the HC and CR have also been confirmed by observations toward Orion-KL using single-dish tele-

scopes and interferometers for line surveys and high-resolution imaging (e.g., Blake et al. 1987; Turner 1989; Turner 1991; Crockett et al. 2015; Liu et al. 2022; Widicus Weaver & Friedel 2012; Friedel & Widicus Weaver 2012; Feng et al. 2015; Tercero et al. 2018; Yamamoto 2016; Peng et al. 2013). The HC region is rich in N-bearing COMs, and the CR region is characterized by abundant O-bearing COMs. The presence of saturated O-bearing species suggests interactions between outflows and quiescent ambient molecular material (Blake et al. 1987). Meanwhile, among O-bearing COMs,  $\text{CH}_3\text{COCH}_3$  has a distribution similar to that of N-bearing COMs, unlike other O-bearing molecules such as  $\text{CH}_3\text{OCHO}$  (Widicus Weaver & Friedel 2012; Peng et al. 2013). Tercero et al. (2018) discussed the spatial distribution differences among O-bearing molecules, focusing on C-O-C and C-O-H bonds.

Observations and chemical modeling have been performed to investigate the origins responsible for the chemical differentiation of N- and O-bearing COMs. Suzuki et al. (2018) evaluated parameters that could influence chemical evolution using the NAUTILUS gas-grain chemical model (Ruaud et al. 2016). Simulations under different physical conditions (e.g., initial densities, warm-up speed, peak density, timescale of the collapsing phase, and peak temperature) revealed that different temperatures play a significant role, whereas the influence of other parameters is relatively minor. Under the assumption that the temperature structures and ages of the cores differ, the observed abundances of NGC 6334F (poor in N-bearing species) and G10.47+0.03 (rich in N-bearing species) were consistent with the chemical model. This suggests that both the different temperature structures inside the core and their evolutionary stages contributed to the observed molecular correlations (Suzuki et al. 2018). Furthermore, Garrod et al. (2022) incorporated nondiffusive reaction processes occurring on dust grain surfaces and within ice mantles into simulations based on the three-phase astrochemical model MAGICKAL (Garrod 2013). The observational results of the hot molecular core (HMC) G31.41+0.31, one of the HMSFRs (Mininni et al. 2023), were consistent within a factor of ten with the abundance ratios predicted by the final chemical models of Garrod et al. (2022). Garrod et al. (2022) suggested that the observed differences in the abundances of N- and O-bearing species may be related to the efficient formation of nitriles in the gas phase during and after ice mantle desorption. They also proposed that the possible duration of chemical reactions in the gas phase after desorption and the thermal history of each source play a significant role in determining its chemical characteristics.

Understanding the chemical differentiation between such N- and O-bearing COMs in the Orion-KL regions and other HMSFRs is also important for comprehending the formation environments and processes of molecules that are considered precursors to prebiotic molecules (e.g.,  $\text{HNCHCN}$  (Zaleski et al. 2013a; Rivilla et al. 2018),  $\text{NH}_2\text{CH}_2\text{CN}$  (Li et al. 2020; Manna & Pal 2022),  $\text{NH}_2\text{CH}_2\text{CH}_2\text{OH}$  (Rivilla et al. 2021), and  $\text{HOCOOH}$  (Sanz-Novo et al. 2023)). Therefore, to evaluate the spectral scan capability, we extracted spectra from the OTF mapping data for the HC and CR regions of Orion-KL, where differences in the abundances of N- and O-bearing COMs have been observed. In addition, we analyzed the spatial distribution of physical quantities to demonstrate the capability of resolving spatial distributions in mapping obser-

<sup>2</sup> <https://splatalogue.online>

vations. We used a  $5' \times 5'$  dataset in 2019 with wide frequency coverage for rotation diagram analysis (Turner 1991) to test the observational capabilities. In addition, observations of distant HMSFRs using interferometers and the nearby Orion-KL region using the B4R on the LMT-50 m have nearly equivalent spatial scales of angular resolution. A comparison of observations on the same spatial scales between distant and nearby objects is pivotal for elucidating the universality of the chemical and physical environments conducive to COMs formation.

This paper is organized as follows. We describe the B4R and report observations and data reductions in Section 2. Section 3 delves into the details of the line identification and the chemical analysis of  $\text{C}_2\text{H}_5\text{CN}$  (N-bearing) and  $\text{CH}_3\text{OCHO}$  (O-bearing). Section 4 presents a comparative analysis of our results with previous results of observations toward Orion-KL and other distant HMSFRs observed with single-dish telescopes and interferometers and discusses their implications. Finally, the main conclusions of this study are summarized in Section 5.

## 2 Observations and data reductions

### 2.1 Band 4 receiver (B4R)

The B4R is a 2 mm single-beam two-polarization heterodyne SIS receiver with 4 K-cooled two sideband (2SB) mixers designed based on the work of Asayama et al. (2014). It was installed in the receiver cabin of the LMT-50 m, marking the commencement of scientific operations (Hughes et al. 2020). The radio frequency (RF) and intermediate frequency (IF) ranges of the B4R are 125–163 GHz and 4–8 GHz, respectively. The receiver noise temperature ( $T_{\text{RX}}$ ) is below 60 K, satisfying the specifications of the Atacama Large Millimeter/submillimeter Array (ALMA) Band 4. The aperture efficiency was measured to be 48% to 33% for 130 to 160 GHz, which is in good agreement with previous measurements for other receivers installed on the LMT (Hughes et al. 2020; Kawabe et al. 2024). The sideband image rejection ratio surpassed 13 dB. Further details can be found in Kawabe et al. (2024).

### 2.2 Observations

This paper presents the results of mapping observations in the spectral line OTF mode conducted using the B4R/LMT-50 m from November 10 to November 29, 2019, encompassing a map size of  $5' \times 5'$  (Kawabe et al. 2024) for testing observational capabilities. Before the OTF observations, the focus, astigmatism, and pointing were corrected using the SiO maser of Orion-KL. The pointing drift between calibrations was typically 3–5'' under stable weather conditions (e.g., wind speed < 10 m/s) (Kawabe et al. 2024). Intensity calibration was performed using the chopper-wheel calibration method, and its accuracy is approximately 10%. The observations were conducted at two 2SB mode frequency settings (set A: 131.4–133.9 GHz and 145.1–147.6 GHz; set B: 136.2–138.7 GHz and 149.9–152.4 GHz). The beam sizes in full width at half maximum (FWHM) were 11.9'' and 10.9'' for set A, and 11.6'' and 10.6'' for set B, as listed in table 1. These beam sizes correspond to approximately 0.02 pc at the distance of Orion-KL ( $\sim 418$  pc; Kim et al. 2008). An eXtended bandwidth Fast Fourier Transform Spectrometer (XFFTS, Radiometer Physics GmbH Co.; Klein et al. 2012) was employed to achieve a frequency resolution of 76.293 kHz, corresponding to a velocity resolution of  $\sim 0.15$ – $0.17$  km/s (2.5 GHz and 32768 channel). The center coordinate of the observation field of view was

$(\alpha, \delta)_{\text{J2000.0}} = (5^{\text{h}}35^{\text{m}}14.^{\text{s}}16, -5^{\circ}22'21''.50)$ , with the OFF point located at  $(\alpha, \delta)_{\text{J2000.0}} = (5^{\text{h}}36^{\text{m}}15.^{\text{s}}50, -5^{\circ}02'34''.40)$ . The total on-source time was approximately 42 min with 3'' scan separations in each frequency set. The telescope elevation range was 65.97–58.84 degrees for set A and 66.05–60.42 degrees for set B, whereas the optical depth  $\tau_{225\text{ GHz}}$  was 0.22 for set A and 0.11 for set B. The system temperatures ( $T_{\text{SYS}}$ ) were measured to be 119 K for set A and 112 K for set B on average for both sidebands, respectively. These observation parameters (observed frequency range, main beam efficiency ( $\eta_{\text{MB}}$ ), beam size ( $\theta_{\text{beam}}$ , FWHM), telescope elevation range,  $\tau_{225\text{ GHz}}$ , and  $T_{\text{SYS}}$ ) for each frequency set are summarized in table 1.

### 2.3 Data reductions

We generated measurement sets from the raw B4R data using the B4R pipeline (b4rpipe), developed by our team<sup>3</sup>. Subsequently, we created FITS datacubes with a grid size of 3'' and a Gaussian grid function using the Common Astronomy Software Applications (CASA) package (The Casa Team et al. 2022).

In OTF observations, which require a relatively long time for mapping, a slight pointing offset can occur owing to the time interval before the next pointing calibration. In sets A and B observations, although pointing calibrations were performed using the SiO maser of Orion-KL before OTF observations, a slight pointing offset was identified in sets A and B OTF maps. By taking advantage of the wide bandwidth, which enables the simultaneous observation of multiple emission lines, it is possible to select the emission lines that are most suitable for pointing offset correction after observations. The procedure for pointing correction is as follows. The HDO and  $\text{HC}_3\text{N}$  ( $v_7 = 2$ ) emission lines were used to calibrate for the pointing offset. The offset relative to the HC was measured using the HDO line, in which the OTF maps showed a point-like distribution, as shown in figure 1. Because HDO is associated with nearly the HC region (e.g., Plambeck & Wright 1987; Neill et al. 2013), the peak coordinates were obtained from the integrated intensity map of the HDO (6(1,6)–5(2,3), upper-level energy  $E_u = 444.03\text{ K}^{4,5}$ ) in set B using 2D Gaussian fitting and then calibrated to the HC coordinates  $(\alpha, \delta)_{\text{J2000.0}} = (5^{\text{h}}35^{\text{m}}14.^{\text{s}}60, -5^{\circ}22'31''.00)$ . The coordinates of each substructure are summarized in table 2 with the CR, BN, and Source I. The calibration shift value for set B was  $(\Delta\alpha, \Delta\delta)_{\text{J2000.0}} = (0.^{\text{s}}455, 4''.811)$ . Then, by using the  $\text{HC}_3\text{N}$  ( $v_7 = 2$ ) emission lines, which are compact distributions and highly excited lines in both set A (16-15,  $l = 0$ ,  $E_u = 701.44\text{ K}^{4,6}$ ) and set B (15-14,  $l = 2f$ ,  $E_u = 697.69\text{ K}^{4,6}$ ), as shown in figure 1, we calibrated set A by matching  $\text{HC}_3\text{N}$  ( $v_7 = 2$ ) peaks coordinate to set B. The calibration shift value for set A was  $(\Delta\alpha, \Delta\delta)_{\text{J2000.0}} = (0.^{\text{s}}360, 9''.73)$ . From the error of the 2D Gaussian fitting and the slight offset between the peaks of HDO and the position of HC (e.g., Plambeck & Wright 1987; Neill et al. 2013), the accuracy of this pointing correction was estimated to be approximately 2–3''. This remained within approximately 30% of the beam size ( $\sim 11''$ ). The baseline calibration over the entire 2.5 GHz bandwidth was performed using the CASA imcontsub task, with a 5th-order polynomial function fitted to line-free channels selected by intensities below  $3\sigma$ .

The HC and CR spectral data were extracted by aver-

### 3 Results

#### 3.1 Line identification and OTF maps

Line identification was performed to test the observational capabilities of spectral scans using the eXtended CASA Line Analysis Software Suite (XCLASS) (Möller et al. 2017) and by referring to the splatalogue<sup>4</sup> database and previous studies. XCLASS refers to two molecular information databases, the Cologne Database for Molecular Spectroscopy (CDMS<sup>6</sup>) (Endres et al. 2016; Müller et al. 2001; Müller et al. 2005) and the Jet Propulsion Laboratory molecular databases (JPL<sup>5</sup>) (Pickett et al. 1998). We performed identifications with a detection threshold of  $3\sigma$  using 0.15–0.17 km/s resolution spectra (non-channel binning). In this analysis, as described in Section 2.3, spectra were extracted by averaging each beam size (table 1) centered on the HC and CR from maps. The effective angular resolution is degraded to approximately 1.4 times the original resolution. As a result, the spectra of HC and CR, which are separated by approximately  $11''$ , are slightly contaminated by each other. However, to perform line identification and evaluate the spatial resolution capability using spectra with improved signal-to-noise ratio (SNR), we adopted the beam size as the averaging region.

As a result, 404 emission lines are detected in the observed frequency ranges, as shown in figures 8–11 in the Appendix. In this study, molecules with more than two emission lines (i.e., two transitions) in the observation frequency ranges are defined as identified. On the other hand, molecules with only one emission line in the observation frequency ranges, with the exception of the recombination line, are defined as tentatively identified. Among the 404 emission lines, 337 lines corresponded to identified or tentatively identified lines. Among the remaining 67 lines, 16 lines were attributed to leakage from the second downconversion or aliasing

from the analog-to-digital converter (ADC) owing to the absence of anti-aliasing filters during this observation. In addition, two lines are ascribed to the leakage of stronger OCS and SO lines from the image sideband to the signal sideband. These 18 leakage emission lines were labeled as X-lines. The remaining 49 lines were labeled as unidentified lines (U-lines). Figures 8–11 and tables 6–8 in the Appendix show detailed information on the spectra of each frequency band, alongside the identified lines, tentatively identified lines, X-lines, and U-lines.

CS and  $\text{C}^{33}\text{S}$  were detected for only one line each. However, we classified them as identified because these lines exhibit sufficient intensity in figures 8–11 in the Appendix, which is consistent with previous studies (Tercero et al. 2010). In the spectra extracted from the HC and CR, only one transition (150.8519 GHz) of cyclic (*c*)- $\text{C}_3\text{H}_2$  was detected, excluding a transition that is blended with a U-line. However, the detection of this transition (150.8519 GHz) is consistent with that of Ziurys & McGonagle (1993), and other transitions (150.8207 GHz) buried in noise in the HC and CR were detected in different regions (e.g., regions west and north of the HC and CR) (Kawabe et al. 2024). Therefore, *c*- $\text{C}_3\text{H}_2$  was classified as an identified species. Second excited torsional states of  $\text{CH}_3\text{OCHO}$  ( $v_t = 2$ ) were identified through comparison with previous studies (Takano et al. 2012; Kobayashi et al. 2013). Consequently,  $\text{H}_3\text{S}\alpha$ ,  $\text{H}_5\text{I}\gamma$  and 29 molecular species, including isotopologues, deuterated molecules, and vibrational excited states, were identified ( $\text{NO}$ ,  $\text{CS}$ ,  $\text{C}^{33}\text{S}$ ,  $\text{SO}$ ,  $^{33}\text{SO}$ ,  $\text{SO}_2$  ( $v = 0, v_2 = 1$ ),  $^{34}\text{SO}_2$ ,  $^{33}\text{SO}_2$ ,  $\text{OCS}$ ,  $\text{O}^{13}\text{CS}$ ,  $\text{HDO}$ ,  $\text{HNCO}$ ,  $\text{H}_2\text{CO}$ ,  $\text{H}_2^{13}\text{CO}$ ,  $\text{H}_2\text{CS}$ , cyclic *c*- $\text{C}_3\text{H}_2$ ,  $\text{HC}_3\text{N}$  ( $v = 0, v_6 = 1, v_7 = 1, v_7 = 2$ ), *t*- $\text{HCOOH}$ ,  $\text{CH}_3\text{CN}$  ( $v = 0, v_8 = 1$ ),  $\text{CH}_3\text{OH}$  ( $v = 0$ ),  $^{13}\text{CH}_3\text{OH}$ ,  $\text{CH}_3\text{CHO}$ ,  $\text{CH}_3\text{CCH}$ ,  $\text{CH}_3\text{NCO}$ ,  $\text{C}_2\text{H}_3\text{CN}$ ,  $\text{CH}_3\text{OCHO}$  ( $v = 0, v_{18} = 1, v_t = 2$ ),  $\text{C}_2\text{H}_5\text{CN}$ ,  $\text{CH}_3\text{OCH}_3$ , and  $\text{CH}_3\text{COCH}_3$ ). A total of 12 molecular species, including excited states, were tentatively identified ( $\text{S}^{18}\text{O}$ ,  $\text{OC}^{33}\text{S}$ ,  $^{18}\text{OCS}$ ,  $^{18}\text{O}^{13}\text{CS}$ ,  $\text{SiS}$ ,  $\text{H}_2\text{C}^{34}\text{S}$ ,  $\text{H}^{13}\text{CCCN}$  ( $v = 0$ ),  $\text{H}(\text{C})\text{OCN}$ ,  $\text{CH}_2\text{DCN}$ ,  $\text{CH}_3^{13}\text{CN}$ ,  $\text{CH}_3\text{OH}$  ( $v_{12} = 1$ ), and  $\text{CH}_3^{18}\text{OH}$ ). The results are summarized in table 3.

O-bearing COMs ( $\text{CH}_3\text{OH}$  ( $v = 0$ ),  $^{13}\text{CH}_3\text{OH}$ ,  $\text{CH}_3\text{CHO}$ ,  $\text{CH}_3\text{OCHO}$  ( $v = 0, v_{18} = 1, v_t = 2$ ),  $\text{CH}_3\text{OCH}_3$ , and  $\text{CH}_3\text{COCH}_3$ ) and N-bearing COMs ( $\text{CH}_3\text{CN}$  ( $v = 0, v_8 = 1$ ),  $\text{C}_2\text{H}_5\text{CN}$ , and  $\text{C}_2\text{H}_3\text{CN}$ ) are detected, as shown in figure 8–11. Notably, N-bearing COMs, such as  $\text{C}_2\text{H}_5\text{CN}$ , exhibit a strong spectral intensity in the HC (blue line), whereas O-bearing COMs, such as  $\text{CH}_3\text{OCHO}$  ( $v = 0$ ) and  $\text{CH}_3\text{OCH}_3$ , exhibit a strong spectral intensity in the CR (red line), as shown in figure 2. Although the spectra of HC and CR are slightly contaminated by each other, the difference in the spectral intensity indicates that the chemical differences between the HC and CR regions are clearly resolved in these observations.

The integrated intensity maps of  $\text{C}_2\text{H}_5\text{CN}$  ( $v = 0$ ) and  $\text{CH}_3\text{OCHO}$  ( $v = 0$ ) are shown in figure 3. The RMSs of the map noise level are  $2.8 \text{ K km s}^{-1}$  and  $0.8 \text{ K km s}^{-1}$  for the observa-

**Fig. 1.** Integrated intensity maps of HDO (left panel) and  $\text{HC}_3\text{N}$  ( $v_7 = 2$ ) (center) in the 136.2–138.7 GHz band and  $\text{HC}_3\text{N}$  ( $v_7 = 2$ ) (right) in the 146.1–147.6 GHz band, after correcting for the main beam efficiency and pointing. The velocity ranges of integrals are  $-5.8$ – $22$   $\text{km s}^{-1}$ ,  $-23$ – $11$   $\text{km s}^{-1}$ , and  $-2.3$ – $22$   $\text{km s}^{-1}$ , respectively. The red cross (+) denotes the hot core and compact ridge. The white cross (x) and star indicate the position of BN and Source I, respectively. The coordinates of each substructure are summarized in table 2. The lower left circle in each panel denotes the beam size in table 1. Alt text: The integrated intensity maps of the three panels. The x axis is the right ascension, and the y axis is the declination at the map size of approximately  $40'' \times 40''$ .

tion settings A and B, respectively. The distributions of  $\text{C}_2\text{H}_5\text{CN}$  ( $v = 0$ ) and  $\text{CH}_3\text{OCHO}$  ( $v = 0$ ) are different.  $\text{C}_2\text{H}_5\text{CN}$  exhibit a peak near the HC, whereas  $\text{CH}_3\text{OCHO}$  exhibit a peak between the HC and CR, as shown in figure 3. The differences in the spectral intensity and the spatial distribution shown in figures 2 and 3 are consistent with those in previous studies (e.g., Feng et al. 2015; Friedel & Widicus Weaver 2012; Tercero et al. 2018) and indicate that the B4R installed on the LMT-50 m can distinguish between the N-bearing COM-rich HC and O-bearing COM-rich CR.

### 3.2 Chemical analysis of $\text{C}_2\text{H}_5\text{CN}$ and $\text{CH}_3\text{OCHO}$

As shown in figure 2, the difference in spectral intensity between N- and O-bearing COMs suggests their spatial segregation across our two regions of interest.  $\text{C}_2\text{H}_5\text{CN}$  and  $\text{CH}_3\text{OCHO}$  are representative N- and O-bearing COMs that have been observed not only in the Orion-KL region but also in distant HMSFRs (e.g., Coletta et al. 2020; Bonfand et al. 2017; Bonfand et al. 2019). In addition,

these lines do not seem to be strongly blended with other molecular lines in our observational data. Therefore, we visualized the spatial distributions as the maps of column densities and rotational temperatures of  $\text{C}_2\text{H}_5\text{CN}$  and  $\text{CH}_3\text{OCHO}$  using the rotation diagram method (Turner 1991) with the advantage of the B4R on the LMT in terms of spatial resolution (i.e., beam size  $\sim 11$ – $12''$ ). The application of the rotation diagram method to maps has also been reported by Bell et al. (2014). The following equations were used in this calculation.

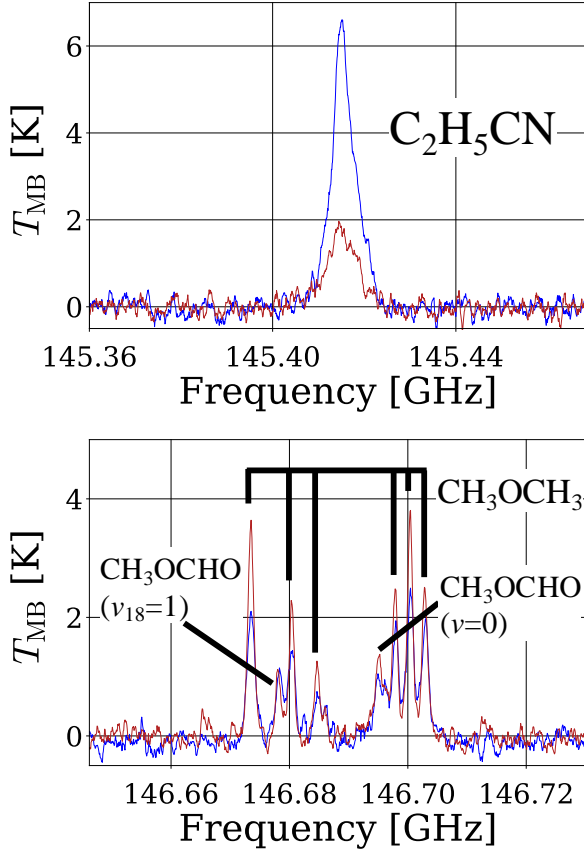

$$\log_{10} \left[ \frac{3kW}{(8\pi^3\nu S\mu^2 g_{\text{I}} g_{\text{K}})} \right] = \log_{10} \left[ \frac{N}{Q(T_{\text{rot}})} \right] - E_{\text{u}} \frac{\log_{10} e}{T_{\text{rot}}}, \quad (1)$$

$$Q(T_{\text{rot}} : \text{C}_2\text{H}_5\text{CN}) = \left[ \frac{\pi(kT_{\text{rot}})^3}{h^3 ABC} \right]^{1/2}, \quad (2)$$

$$Q(T_{\text{rot}} : \text{CH}_3\text{OCHO}) = 2 \left[ \frac{\pi(kT_{\text{rot}})^3}{h^3 ABC} \right]^{1/2}, \quad (3)$$

where  $W$ ,  $\nu$ ,  $k$ ,  $h$ ,  $\mu$ ,  $S$ ,  $E_{\text{u}}$ ,  $g_{\text{I}}$ ,  $g_{\text{K}}$ ,  $N$ ,  $Q$ , and  $T_{\text{rot}}$  represent the integrated intensity, frequency, Boltzmann constant, Planck constant, dipole moment, line strength, upper-level energy, nuclear spin degeneracy,  $K$ -level degeneracy, column density, partition function, and rotational temperature, respectively.  $A$ ,  $B$ , and  $C$  in equations (2) and (3) indicate the rotational constants for the three principal axes of each molecule.

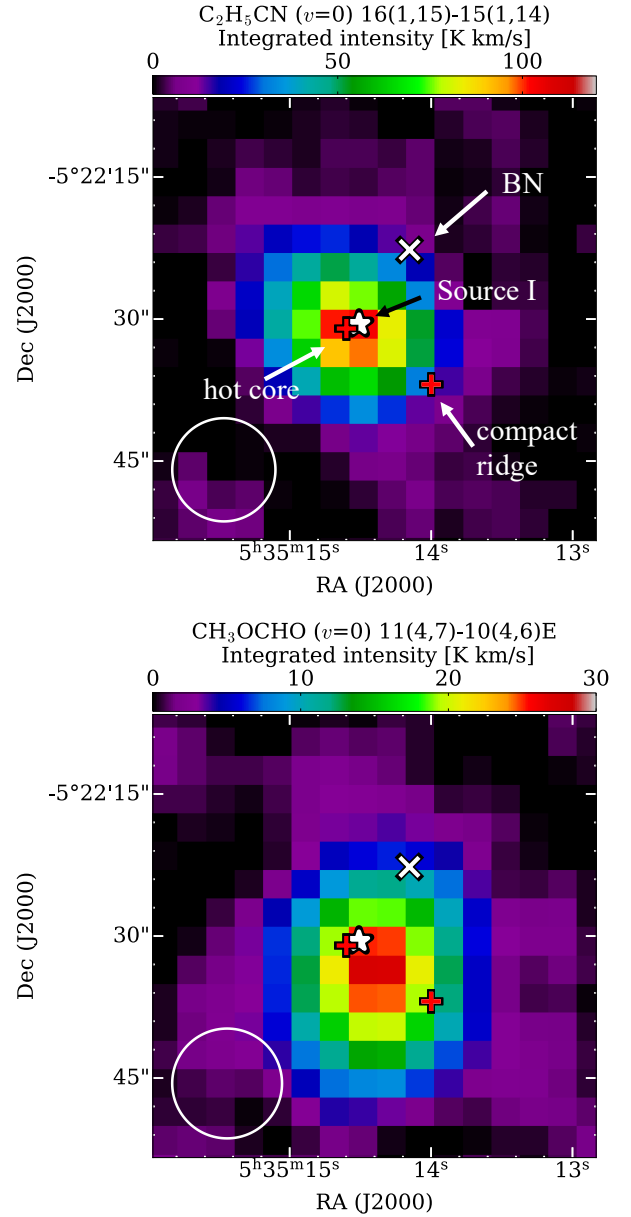

To apply the rotation diagram method to the maps, we used the spectra of  $\text{C}_2\text{H}_5\text{CN}$  and  $\text{CH}_3\text{OCHO}$  extracted by averaging each beam size at the HC and CR (Section 3.1) as a reference. In this reference spectrum, transitions with a spectral intensity of more than  $4\sigma$  in both the HC and CR regions, and that are not blended with other emission lines, were used in the calculations for all pixels.  $\text{CH}_3\text{OCHO}$  has two types of rotational transitions, ground torsional states ( $v = 0$ ) and first excited torsional states ( $v_{18} = 1$ ), in the emission lines above  $4\sigma$ . Therefore, calculations were performed using only the ground torsional state ( $v = 0$ ) and both torsional states ( $v = 0$  and  $v_{18} = 1$ ). Consequently, 8  $\text{C}_2\text{H}_5\text{CN}$ , 25  $\text{CH}_3\text{OCHO}$  ( $v = 0$ ), and 34  $\text{CH}_3\text{OCHO}$  ( $v = 0$  and  $v_{18} = 1$ ) transitions were used in this calculation. The degeneracies of  $\text{C}_2\text{H}_5\text{CN}$  are  $g_{\text{I}} = g_{\text{K}} = 1$ . Both A- and E-type transitions were observed

**Fig. 2.** Spectra of  $\text{C}_2\text{H}_5\text{CN}$ ,  $\text{CH}_3\text{OCHO}$  ( $v=0$ ,  $v_{18}=1$ ), and  $\text{CH}_3\text{OCH}_3$  in the 145.1–147.6 GHz band. The blue and red lines represent spectra with 10-channel binning, averaging in circles with diameters corresponding to the beam size of  $10.9''$  centered at the HC and CR (Feng et al. 2015), respectively. Alt text: The molecular emission line spectra of the two panels. The x axis is the frequency in gigahertz, and the y axis is the intensity at kelvin on the  $T_{\text{MB}}$  scale.

for  $\text{CH}_3\text{OCHO}$ .  $g_{\text{I}} = 2$  and  $g_{\text{K}} = 1$  for A-type transitions, whereas  $g_{\text{I}} = 1$  and  $g_{\text{K}} = 2$  for E-type transitions (Turner 1991). In this study, both A- and E-type transitions were used together for fitting; thus, the column density includes contributions from both types. The formulation of  $Q$  (equations (2) and (3)) was adopted from Turner (1991). Because  $\text{CH}_3\text{OCHO}$  has A- and E-type transitions, the partition function of  $\text{CH}_3\text{OCHO}$  (equation (3)) is multiplied by 2. The values of  $A$ ,  $B$ , and  $C$  were obtained from Fukuyama et al. (1996) for  $\text{C}_2\text{H}_5\text{CN}$  and from Karakawa et al. (2001) for  $\text{CH}_3\text{OCHO}$ . The values of  $\nu$ ,  $S\mu^2$ , and  $E_{\text{u}}$  were obtained from the JPL database. The integrated intensity maps calculated from the OTF observations of 8  $\text{C}_2\text{H}_5\text{CN}$  lines and 34  $\text{CH}_3\text{OCHO}$  ( $v=0$  and  $v_{18}=1$ ) lines, which have intensities above  $4\sigma$  in the spectra extracted by averaging each beam size at the HC and CR, were fitted pixel-by-pixel using equation (1), resulting in maps of  $N$  and  $T_{\text{rot}}$ . The beam size of these maps was aligned to  $12''$  using CASA.

The relative abundances with respect to  $\text{H}_2$  ( $X = N/N(\text{H}_2)$ ) were calculated. The values of  $N(\text{H}_2)$  are acquired from the FITS maps reported by Schuller et al. (2021). The  $N(\text{H}_2)$  map has an angular resolution of  $8''$ . This map was calculated using SPIRE 160, 250, 350, and  $500 \mu\text{m}$  data from the Herschel Gould Belt Survey (André et al. 2010) and ArTéMiS 350 and  $450 \mu\text{m}$

**Fig. 3.** Integrated intensity maps of  $\text{C}_2\text{H}_5\text{CN}$  ( $v=0$ ) (upper panel) in the 145.1–147.6 GHz band and  $\text{CH}_3\text{OCHO}$  ( $v=0$ ) (lower) in the 136.2–138.7 GHz band, after correcting for the main beam efficiency and pointing. The velocity ranges of integrals are  $-40$ – $40 \text{ km s}^{-1}$  and  $0$ – $20 \text{ km s}^{-1}$ , respectively. The various sources indicated on each map are described in figure 1 and table 2. The lower left circle in each panel denotes the beam size in table 1. Alt text: Integrated intensity maps of the two panels. The x axis is the right ascension, and the y axis is the declination at the map size of approximately  $40'' \times 40''$ .

data. Previous studies (e.g., Suzuki et al. 2018; Suzuki et al. 2016; Comito et al. 2005) have shown that assuming a conservative  $10''$  source size is an effective method for estimating the relative abundances, because the results agree well with other previous studies within the margin of error. In this study, we also assumed a  $10''$  source size to compare with the results of Suzuki et al. (2018) and to evaluate the observational capability of the B4R on the LMT-50 m. In addition to  $N$ ,  $T_{\text{rot}}$ , and  $X$ , which were calculated from data with a beam size of  $12''$ ,  $N'$ ,  $T'_{\text{rot}}$ , and  $X'$  in the

HC and CR were calculated assuming a source size of  $10''$  based on Suzuki et al. (2018). We adjusted the beam size of the  $N(\text{H}_2)$  map from  $8''$  to  $12''$  and  $10''$  using CASA and calculated the  $1\sigma$  error from the standard deviations of  $12''$  and  $10''$ . The  $N(\text{H}_2)$  values in the HC and CR regions are  $(5.5 \pm 0.1) \times 10^{23} \text{ cm}^{-2}$  and  $(4.0 \pm 0.2) \times 10^{23} \text{ cm}^{-2}$ , at  $12''$ , respectively. At  $10''$ , the  $N(\text{H}_2)$  values in the HC and CR regions are  $(5.8 \pm 0.1) \times 10^{23} \text{ cm}^{-2}$  and  $(4.1 \pm 0.3) \times 10^{23} \text{ cm}^{-2}$ , respectively. The maps of  $N$ ,  $T_{\text{rot}}$ , and  $X$  for  $\text{C}_2\text{H}_5\text{CN}$  and  $\text{CH}_3\text{OCHO}$  ( $v = 0$  and  $v_{18} = 1$ ) are shown in figure 4, whereas the rotation diagram plots for the HC and CR are shown in figure 5. The column density, the rotational temperature, and the relative abundance maps are masked above the maximum around the HC and CR, as shown in figure 4. The  $1\sigma$  noise of  $W$  is expressed as error bars in the rotation diagram plots (figure 5). The  $N$ ,  $T_{\text{rot}}$ ,  $X$ ,  $N'$ ,  $T'_{\text{rot}}$ , and  $X'$  values in the HC and CR regions of  $\text{C}_2\text{H}_5\text{CN}$ ,  $\text{CH}_3\text{OCHO}$  ( $v = 0$ ), and  $\text{CH}_3\text{OCHO}$  ( $v = 0$  and  $v_{18} = 1$ ) are listed in table 4. In table 4, we show the fitting results for only the 25  $\text{CH}_3\text{OCHO}$  ( $v = 0$ ) transitions as well as the fitting results using data for 34  $\text{CH}_3\text{OCHO}$  ( $v = 0$  and  $v_{18} = 1$ ) transitions. The errors in  $N$ ,  $T_{\text{rot}}$ ,  $N'$ , and  $T'_{\text{rot}}$  were calculated from the  $1\sigma$  error obtained by fitting, considering error propagation and adding 10% of the main values as the absolute calibration error. The errors in  $N$  and  $N'$  also take into account the uncertainty of the rotation temperature in the calculation of the partition function.

Figure 4 shows that the  $X(\text{C}_2\text{H}_5\text{CN})$  and  $X(\text{CH}_3\text{OCHO})$  of Orion-KL observed at the  $0.02 \text{ pc}$  scale differs between the HC and the CR, indicating that the difference is not due to the total gas abundance but to the chemical properties.  $X(\text{C}_2\text{H}_5\text{CN})$  shows a maximum near the HC and is approximately four times stronger than that observed in the CR.  $X(\text{CH}_3\text{OCHO})$  shows a peak in the region between the HC and CR. In addition,  $X(\text{C}_2\text{H}_5\text{CN})$  has a compact distribution, whereas  $X(\text{CH}_3\text{OCHO})$  has a more extended distribution in figure 4. Although previous studies (e.g., Suzuki et al. 2018; Feng et al. 2015) have determined the temperatures in specific regions, such as the HC and CR, the temperature map in figure 4 shows the continuous temperature distributions in COMs around the HC and CR, as shown in the temperature maps of  $\text{CH}_3\text{CN}$  reported by Bell et al. (2014). Figure 4 shows a broad distribution at approximately  $100 \text{ K}$  for the  $T_{\text{rot}}$  of  $\text{CH}_3\text{OCHO}$ ; however, it shows that a high-temperature region exists northeast of the HC for the  $T_{\text{rot}}$  of  $\text{C}_2\text{H}_5\text{CN}$ , i.e.,  $\text{CH}_3\text{OCHO}$  and  $\text{C}_2\text{H}_5\text{CN}$  have different temperature distributions.

## 4 Discussion

### 4.1 Comparison of line identification with previous studies

Sulfur oxide molecules and sulfur carbon chain molecules, such as  $\text{SO}_2$  ( $v = 0, v_2 = 1$ ),  $^{34}\text{SO}_2$ ,  $\text{SO}$ ,  $^{33}\text{SO}$ ,  $^{33}\text{SO}_2$ ,  $\text{O}^{13}\text{CS}$ ,  $\text{OCS}$ ,  $\text{H}_2\text{CS}$ ,  $\text{CS}$ , and  $\text{C}^{33}\text{S}$ , were identified. This identification is consistent with previous studies toward Orion-KL conducted at the Institut de radioastronomie millimétrique (IRAM)-30 m (Tercero et al. 2010; Esplugues et al. 2013).  $\text{S}^{18}\text{O}$ ,  $\text{OC}^{33}\text{S}$ ,  $^{18}\text{OCS}$ ,  $\text{H}_2\text{C}^{34}\text{S}$ , and  $\text{SiS}$  (silicon-bearing molecules) were labeled tentatively identified. However, their detection in previous studies toward Orion-KL (Tercero et al. 2010; Tercero et al. 2011; Esplugues et al. 2013) substantiates the reliability of our detection. The spectra of these molecules, excluding the tentative lines, are shown in figure 6.

Five lines that were unidentified in the Orion-KL region  $2 \text{ mm}$  band line survey by the Taeduk Radio Astronomy Observatory (TRAO)-14 m (Lee et al. 2001) and the Five College Radio

Astronomical Observatory (FCRAO)-14 m (Ziurys & McGonagle 1993), were identified in this study as  $\text{C}_2\text{H}_3\text{CN}$  ( $138.39516 \text{ GHz}$ ),  $\text{HC}_3\text{N}$  ( $v_7 = 1$ ) ( $146.1276387 \text{ GHz}$ ),  $\text{S}^{18}\text{O}$  ( $145.8738078 \text{ GHz}$ , tentatively identified),  $\text{CH}_3\text{OCH}_3$  ( $150.594406 \text{ GHz}$ ), and  $\text{CH}_3\text{OH}$  ( $v_{12} = 1$ ) ( $150.282794 \text{ GHz}$ , tentatively identified), as shown in figure 8–11. In addition, 162 previously undetected lines, with the exception of X-lines (Lee et al. 2001; Ziurys & McGonagle 1993) were newly detected, and 142 lines were identified in this study. The remaining 20 lines were labeled U-lines in this study. The line previously identified as  $\text{CH}_3\text{OCH}_3$  at  $150.4673 \text{ GHz}$  by Lee et al. (2001) was labeled a U-line in this study. Despite the short integration time, these results demonstrate the sufficient performance of the B4R receiver.

### 4.2 Comparison of chemical properties with results from previous studies

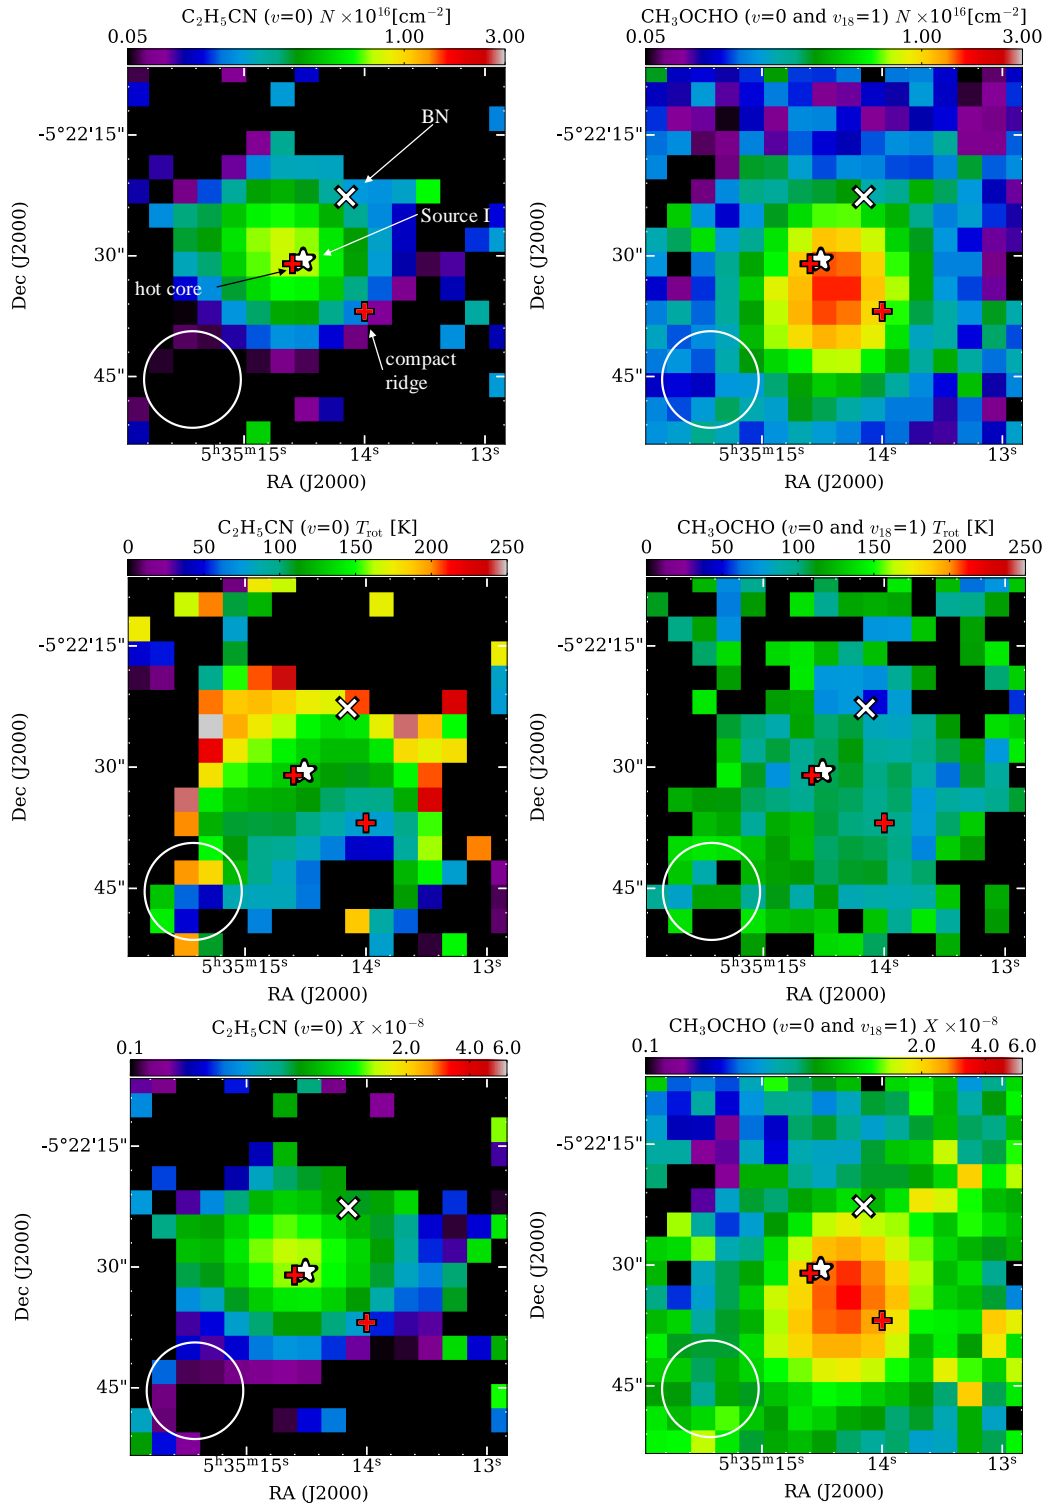

#### 4.2.1 Orion-KL

The  $N$ ,  $T_{\text{rot}}$ ,  $N'$ , and  $T'_{\text{rot}}$  values of  $\text{CH}_3\text{OCHO}$  ( $v = 0$ ) and  $\text{C}_2\text{H}_5\text{CN}$  in the HC (table 4) are consistent with the results from the Nobeyama Radio Observatory (NRO)-45 m centered nearly on the HC (assuming a source size of  $10''$ , Suzuki et al. 2018). Their  $X$  and  $X'$  values are lower than those reported by Suzuki et al. (2018). This is likely because the  $N(\text{H}_2)$  values used by Suzuki et al. (2018) were obtained from observations with a large beam size, leading to an underestimation of  $N(\text{H}_2)$ . All values of  $\text{CH}_3\text{OCHO}$  ( $v = 0$  and  $v_{18} = 1$ ) at the HC and CR are lower than those reported by Feng et al. (2015). This difference is expected because their observations were performed using an interferometer, which provided a smaller synthetic beam, approximately  $6'' \times 4''$  (Feng et al. 2015).

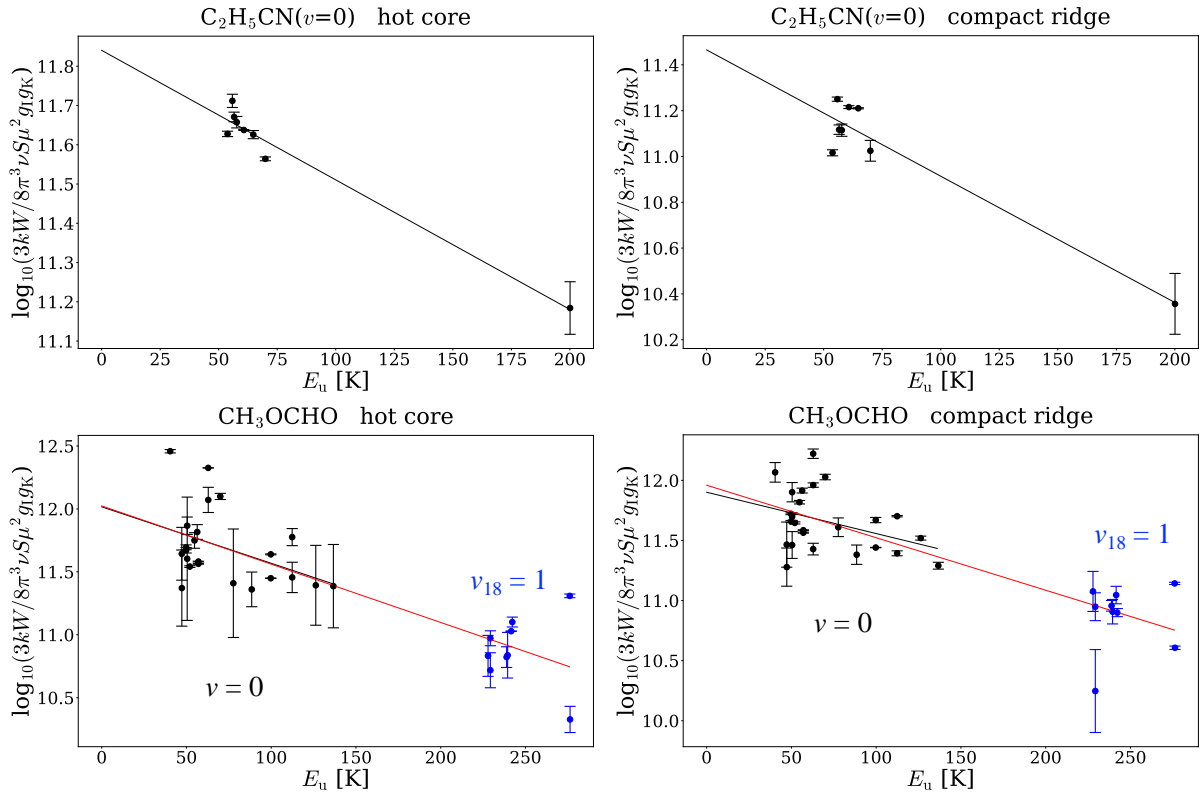

The distribution of  $\text{C}_2\text{H}_5\text{CN}$  centered around the HC resembles the integrated intensity maps obtained using interferometers, such as the Submillimeter Array (SMA), IRAM-30 m (Feng et al. 2015), and the Combined Array for Research in Millimeter-wave Astronomy (CARMA, Friedel & Widicus Weaver 2012). The distribution of  $\text{CH}_3\text{OCHO}$  extending between the HC and CR is consistent with the integrated intensity distributions obtained from the SMA and IRAM-30 m (Feng et al. 2015), ALMA (Tercero et al. 2018), and CARMA (Friedel & Widicus Weaver 2012). The existence of a high-temperature region northeast of the HC of  $T_{\text{rot}}$  in  $\text{C}_2\text{H}_5\text{CN}$  is similar to that in  $\text{CH}_3\text{CN}$  observed at IRAM-30 m (Bell et al. 2014). This high-temperature region traced by  $\text{CH}_3\text{CN}$  is thought to be caused by shock heating from northeast-southwest outflow gas (Plambeck et al. 2009), which originates from active star formation near IRc2 (Bell et al. 2014). In addition, the distributions of  $N$  and  $X$  in  $\text{C}_2\text{H}_5\text{CN}$ , which show a peak near the HC, are similar to the distributions of  $N$  and  $X$  in the map of  $\text{CH}_3\text{CN}$  reported by Bell et al. (2014). The formation process of  $\text{C}_2\text{H}_5\text{CN}$  on grains is related to  $\text{CH}_3\text{CN}$  (e.g., Garrod 2013; Garrod et al. 2017; Garrod et al. 2022), and shocks are considered the most plausible mechanism for releasing  $\text{C}_2\text{H}_5\text{CN}$  from dust grain surfaces (e.g., Friedel & Widicus Weaver 2012). The existence of a similar high-temperature region in  $\text{C}_2\text{H}_5\text{CN}$  and  $\text{CH}_3\text{CN}$ , as well as the similarity of the distributions of column density  $N$  and abundance  $X$ , which has a peak around the HC, reinforce the strength of the physical/chemical relationship between  $\text{C}_2\text{H}_5\text{CN}$  and  $\text{CH}_3\text{CN}$ .

#### 4.2.2 Other high-mass star-forming regions

COMs have been detected across various regions, and astrochemical studies, including N- and O-bearing COMs toward distant

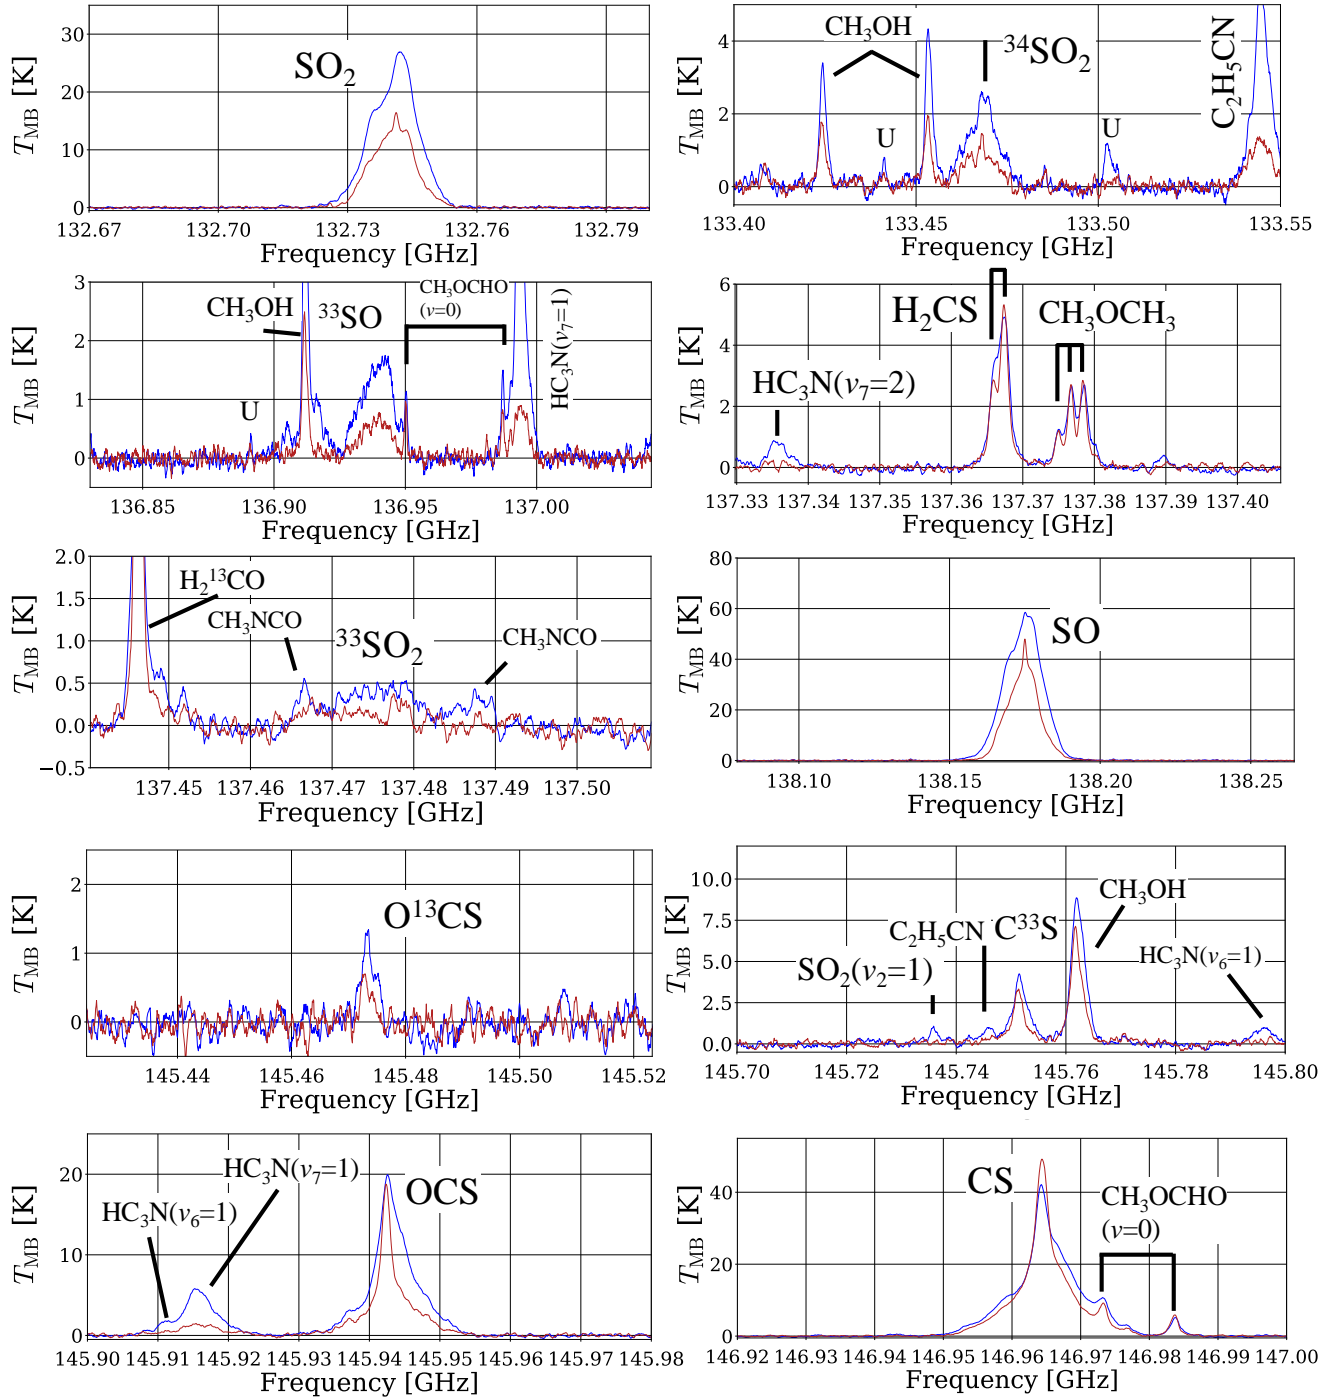

**Fig. 4.** Column density  $N$  (upper row), rotational temperature  $T_{rot}$  (middle), and relative abundance with respect to  $H_2$   $X$  (lower) maps of  $C_2H_5CN$  (left column) and  $CH_3OCHO$  ( $v=0$  and  $v_{18}=1$ ) (right). The various sources indicated on each map are described in figure 1 and table 2. The lower left circle in each panel denotes the beam size (12''). The column density, the rotational temperature, and the abundance maps are masked above the maximum around the HC and CR. Alt text: The column density, rotational temperature, and relative abundance with respect to  $H_2$  maps of the six panels. The x axis is the right ascension, and the y axis is the declination at map size of approximately  $40'' \times 40''$ .

**Fig. 5.** Rotation diagram plots of  $\text{C}_2\text{H}_5\text{CN}$  and  $\text{CH}_3\text{OCHO}$  ( $v = 0$  and  $v_{18} = 1$ ) for the HC and CR ( $12''$ ). The error bars indicate the  $1\sigma$  noise of  $W$ . The upper panels show the plots of  $\text{C}_2\text{H}_5\text{CN}$ . In the lower panels, the black plots are  $\text{CH}_3\text{OCHO}$  ( $v = 0$ ) and the blue plots are  $\text{CH}_3\text{OCHO}$  ( $v_{18} = 1$ ). The black line shows the fitting result using only ( $v = 0$ ) states in each panel. The red line represents the fitting result using both torsional states  $\text{CH}_3\text{OCHO}$  ( $v = 0$  and  $v_{18} = 1$ ). Alt text: The rotation diagram plots of the four panels. The x axis is the upper-level energy at kelvin, and the y axis is the left side of equation (1).

**Table 4.** Column density, rotational temperature, and relative abundance with respect to  $\text{H}_2$  of  $\text{C}_2\text{H}_5\text{CN}$ ,  $\text{CH}_3\text{OCHO}$  ( $v = 0$ ), and  $\text{CH}_3\text{OCHO}$  ( $v = 0$  and  $v_{18} = 1$ ).

The blue and red lines represent spectra with 10-channel binning, averaging in circles with diameters corresponding to the beam size for each frequency band (table 1, 11–12'') centered at the HC and CR (Feng et al. 2015), respectively. Lines labeled with "U" denote undefined lines. Alt text: The molecular emission line spectra of the ten panels. The x axis is the frequency at gigahertz, and the y axis is the intensity at kelvin on the  $T_{\text{MB}}$  scale.

HMSFRs, such as Sgr B2(N) and G10.47+0.03, have been extended (e.g., McGuire 2022; Coletta et al. 2020; Bonfand et al. 2017; Bonfand et al. 2019; Qin et al. 2022; Li et al. 2020; Qin et al. 2015; Belloche et al. 2009; Manna & Pal 2023; Busch et al. 2024; Armijos-Abendaño et al. 2014; Rolffs et al. 2011; Mininni

et al. 2023; Zeng et al. 2018). Spatial distribution differences between N- and O-bearing COMs have been observed in some HMSFRs (e.g., Wyrowski et al. 1999; Kalenskii & Johansson 2010; Remijan et al. 2004; Zernickel et al. 2012; Allen et al. 2017; van der Walt et al. 2021; Peng et al. 2022; Mininni et al.

2023).

Figure 4 shows the differences in the distributions and abundances of  $\text{C}_2\text{H}_5\text{CN}$  and  $\text{CH}_3\text{OCHO}$  in the Orion KL region. The difference in spatial distributions between  $\text{C}_2\text{H}_5\text{CN}$  and  $\text{CH}_3\text{OCHO}$  was more pronounced when the spatial resolution was higher ( $\sim 2\text{--}6''$ ) as shown in previous interferometric observations (Feng et al. 2015; Friedel & Widicus Weaver 2012; Tercero et al. 2018). These results contrast with previous 2 mm band observations using the IRAM-30 m telescope, which revealed that  $X(\text{C}_2\text{H}_5\text{CN})$  and  $X(\text{CH}_3\text{OCHO})$  are strongly correlated for eight HMSFRs (18089-1732, G31.41+0.03, G24.78+0.08, W3(OH), G14.33-0.65, W51, G10.47+0.03, and G29.96-0.02) at distances of 2.0–8.9 kpc (Coletta et al. 2020). The beam size in the half power beam width (HPBW,  $\theta_{\text{beam}}$ ) of the IRAM-30 m in the 2 mm band was approximately  $16\text{--}18''$  (Coletta et al. 2020). This beam size corresponds to the spatial scale of the angular resolution ( $S_{\text{beam}}$  [pc]) of approximately 0.16–0.73 pc at distances of 2.0–8.9 kpc, and it is an order of magnitude larger than the 0.02 pc in this study. The beam size that Coletta et al. (2020) ( $16\text{--}18''$ ) used to calculate the column densities is smaller than that of the observation ( $\theta_{\text{H}_2}=20\text{--}60''$ ) used to calculate  $N(\text{H}_2)$  for calculating  $X$ . Therefore, Coletta et al. (2020) rescaled the column densities by  $(\theta_{\text{beam}}/\theta_{\text{H}_2})^2$  to match the spatial scales of  $N$  and  $N(\text{H}_2)$  when  $X$  was derived. Consequently, the apparent  $S_{\text{beam}}$  of  $X(\text{C}_2\text{H}_5\text{CN})$  and  $X(\text{CH}_3\text{OCHO})$  became even larger. We focused on  $S_{\text{beam}}$  to understand the significance of the correlation between  $X(\text{C}_2\text{H}_5\text{CN})$  and  $X(\text{CH}_3\text{OCHO})$ . The good correlation between  $X(\text{C}_2\text{H}_5\text{CN})$  and  $X(\text{CH}_3\text{OCHO})$ , despite the existence of regions with different abundances in the same source, such as Orion-KL, may be due to the observational resolution.

HMSFRs evolve from high-mass starless cores (HMSCs) to high-mass protostellar objects (HMPOs). As protostars form, these evolve into hot molecular cores (HMCs). Subsequently, these protostars heat the surroundings, forming hypercompact H II regions (HCHII). Further evolution results in classification into ultracompact H II regions (UCHII) and eventually H II regions (e.g., van Dishoeck & Blake 1998; Tan et al. 2014; Yamamoto 2016; Coletta et al. 2020). In Coletta et al. (2020), the phase between HMPOs and UCHII, encompassing HCHII and phases containing high-mass sources, is termed the intermediate (INT) phase. Eight sources studied by Coletta et al. (2020), 18089-1732(INT), G31.41+0.03 (INT), G24.78+0.08 (INT), W3(OH) (UCHII), G14.33-0.65 (UCHII), W51 (UCHII), G10.47+0.03 (UCHII), and G29.96-0.02 (UCHII), were selected from previous studies (Fontani et al. 2011; Fontani et al. 2014; Fontani et al. 2015a; Fontani et al. 2015b; Fontani et al. 2016; Fontani et al. 2018; Fontani et al. 2019; Colzi et al. 2018b; Colzi et al. 2018a; Mininni et al. 2018).

A similar linear scale  $S_{\text{beam}}$  with Orion-KL in this study ( $S_{\text{beam}} \approx 0.02$  pc) is expected for a target at a distance of several kpc when it is observed with a spatial resolution of beam sizes of  $\sim 1\text{--}2''$  using interferometers. In this case, a direct comparison is allowed between Orion KL and more distant sources, which are several kpc away. Therefore, we selected Sgr B2 (Bonfand et al. 2017; Bonfand et al. 2019; Busch et al. 2024; Sánchez-Monge et al. 2017; Meng et al. 2022), which was observed by interferometers ( $\theta_{\text{beam}} \approx 1\text{--}2''$ ) and has a similar  $S_{\text{beam}}$  to Orion-KL in this study, as a comparison target to compare  $X(\text{C}_2\text{H}_5\text{CN})$  and  $X(\text{CH}_3\text{OCHO})$  with the eight sources with  $S_{\text{beam}} > 0.1$  from Coletta et al. (2020). The information for each source is presented in table 5. The classification of the evolutionary stage was based on Coletta et al. (2020); Gerner et al. (2014); Gerner et al.

(2015); Bonfand et al. (2017).  $\theta_{\text{beam}}$  and  $\theta_{\text{H}_2}$  represent the beam sizes of the telescopes.  $S_{\text{beam}}$  denotes the spatial scale of the angular resolution calculated from  $\theta_{\text{beam}}$  and the distance.

Figure 7 shows  $X(\text{C}_2\text{H}_5\text{CN})$  and  $X(\text{CH}_3\text{OCHO})$  of the sources listed in table 5. The color scale corresponds to  $S_{\text{beam}}$  [pc]. The results of the eight sources from Coletta et al. (2020) (18089-1732, G31.41+0.03, G24.78+0.08, W3(OH), G14.33-0.65, W51, G10.47+0.03, and G29.96-0.02) are based solely on the transition of  $\text{CH}_3\text{OCHO}$  ( $v = 0$ ). Therefore, the plots for the HC and CR in Orion-KL utilized values of  $X(\text{CH}_3\text{OCHO}$  ( $v = 0$ )) from table 4. The solid black line represents the fitting and correlation for the eight sources with  $S_{\text{beam}} > 0.1$  pc (18089-1732, G31.41+0.03, G24.78+0.08, W3(OH), G14.33-0.65, W51, G10.47+0.03, and G29.96-0.02) (Coletta et al. 2020). The spatial resolutions of the observations for Orion-KL and Sgr B2 ( $S_{\text{beam}} < 0.1$  pc) are similar to each other but smaller than those of the other eight sources ( $S_{\text{beam}} > 0.1$  pc). Therefore, we applied an independent fitting for Orion-KL and Sgr B2. The black dashed line in figure 7 is the result of a linear fit for Orion-KL (HC and CR, not assuming source size) and Sgr B2 (N1:SE1, N1:NW3, N2, N3, N4, N5) simultaneously. Sgr B2(N1:SE1) and Sgr B2(N1:NW3) denote observations performed at approximately 0.1 pc southeast and northwest of Sgr B2 (N1), respectively (Busch et al. 2024). The results for these sources with  $S_{\text{beam}}$  smaller than 0.1 pc show a large dispersion, with a correlation coefficient of  $r = 0.57$ . The correlation coefficient remains similar ( $r = 0.54$ ) even when  $X'$  (assuming a source size of  $10''$ ) is used in place of  $X$ .

This correlation coefficient is lower than the value reported by Coletta et al. (2020) ( $r = 0.92$ ). Additionally, the solid line (Coletta et al. 2020) shifts below the dashed line (in this study) and is closer to the values of  $X(\text{C}_2\text{H}_5\text{CN})$  and  $X(\text{CH}_3\text{OCHO})$  in the CR (inverted triangle) than in the HC (triangle) in Orion-KL, as shown in figure 7. This indicates that the eight sources with  $S_{\text{beam}} > 0.1$  pc tend to have relatively high  $X(\text{CH}_3\text{OCHO})$  values. These considerations highlight the dependence of  $X$  on  $S_{\text{beam}}$ , indicating that coarser resolution observations ( $S_{\text{beam}} > 0.1$  pc) may not adequately resolve regions with distinct chemical properties. In this case,  $\text{CH}_3\text{OCHO}$  (O-bearing COMs), which is more widely distributed and highly abundant, may be predominantly observed, compared with  $\text{C}_2\text{H}_5\text{CN}$  (N-bearing COMs), which is relatively compactly distributed, as shown in figure 4.

The integrated intensity maps obtained from interferometric observations of G10.47+0.03 (Rolfs et al. 2011) and W3(OH) (Wyrowski et al. 1999), which are included among the eight sources, support this suggestion. The integrated intensity distributions of  $\text{C}_2\text{H}_5\text{CN}$  and  $\text{CH}_3\text{OCHO}$  obtained with a beam size of approximately  $4'' \times 2''$  ( $S_{\text{beam}} \approx 0.11 \times 0.06$  pc) using SMA are similar (Rolfs et al. 2011). However, the map observed with a smaller beam size (approximately  $0.5'' \times 0.3''$ , corresponding to  $S_{\text{beam}} \approx 0.01 \times 0.008$  pc) shows that the intensity distribution differs, with  $\text{CH}_3\text{OCHO}$  having a peak on the west side and  $\text{C}_2\text{H}_5\text{CN}$  having a peak on the east side. In addition,  $\text{CH}_3\text{OCHO}$  is more widely distributed than  $\text{C}_2\text{H}_5\text{CN}$  (Rolfs et al. 2011). The differences in the distributions of  $\text{C}_2\text{H}_5\text{CN}$  and  $\text{CH}_3\text{OCHO}$  and the extended distribution of  $\text{CH}_3\text{OCHO}$  at  $S_{\text{beam}} < 0.1$  are similar in this study. Additionally, these features are also observed in the integrated intensity map of W3(OH) from observations with the Plateau de Bure Interferometer (PdBI) ( $\theta_{\text{beam}} \approx 0.8'' \times 0.6''$ , corresponding to  $S_{\text{beam}} \approx 0.008 \times 0.006$  pc) (Wyrowski et al. 1999). Therefore, although a precise analysis of the abundances of  $\text{C}_2\text{H}_5\text{CN}$  and  $\text{CH}_3\text{OCHO}$  in each region is necessary, these detailed maps observed with the SMA and PdBI support the above suggestions.

**Table 5.** High-mass star-forming regions in each observation.

The comparison of  $X(\text{C}_2\text{H}_5\text{CN})$  and  $X(\text{CH}_3\text{OCHO})$  focusing on  $S_{\text{beam}}$  in this study confirms that  $\text{CH}_3\text{OCHO}$  may be predominantly observed in coarser resolution observations ( $S_{\text{beam}} > 0.1$ ), as suggested by interferometric results. The good correlation between  $X(\text{C}_2\text{H}_5\text{CN})$  and  $X(\text{CH}_3\text{OCHO})$  may be affected by the extent to which the spatial scale of such angular resolution includes each molecular distribution with different spatial coverages due to differences in the physical and chemical environments. To gain a more detailed understanding of the relationship between  $X(\text{C}_2\text{H}_5\text{CN})$  and  $X(\text{CH}_3\text{OCHO})$ , it is necessary to observe the differences in their abundances and spatial distributions across sources by observing distant astronomical objects with a spatial resolution sufficient to resolve individual sources.

In the Sgr B2(N) region, where  $X(\text{C}_2\text{H}_5\text{CN})$  appeared higher (positioned upward in figure 7), some prebiotic molecules, such as  $\text{H}_2\text{C}_2\text{N}_2$  (Z-(E)-HNCHCN) and  $\text{H}_2\text{C}_4\text{N}_2$  ( $\text{NH}_2\text{CH}_2\text{CN}$ ), have also been observed (Zaleski et al. 2013b; Belloche et al. 2008; Li et al. 2020). G10.47+0.03 is expected to contain a region with a high  $X(\text{C}_2\text{H}_5\text{CN})$  (Rolfs et al. 2011), similar to the Sgr B2(N) and Orion-KL HC regions.  $\text{NH}_2\text{CH}_2\text{CN}$  was also detected in G10.47+0.03 (Manna & Pal 2022). In addition, chemical model calculations suggest that the Orion-KL region is a probable source for detecting Z-(E)-HNCHCN (Zhang et al. 2020). The angular resolution of B4R/LMT-50 m enables us to resolve a 0.02 pc structure at the distance of Orion-KL, and owing to the wide bandwidth, many molecular emission lines can be observed simultaneously. These capabilities in nearby star-forming regions such as Orion-KL potentially complement detailed high angular resolution studies on distant sources using interferometers with similar  $S_{\text{beam}}$  at several kpcs and arcseconds. The B4R/LMT-50 m capabilities could help us understand the formation of prebiotic molecules and the observed differences in  $X(\text{C}_2\text{H}_5\text{CN})$  and  $X(\text{CH}_3\text{OCHO})$  across various sources.

### 4.3 Future upgrades and prospects of B4R system

The B4R and observation system are being developed (Kawabe et al. 2024). In May 2024, remote tuning of the LO power at each frequency setting to minimize the receiver noise temperature and monitoring of key parameters (e.g., the temperature of the 4K stage and vacuum gauge output) were integrated and are now ready for future use. The expansion of the IF bandwidth by adding two XFFTS boards has already been prepared and is expected to be integrated in the near future. Furthermore, efforts are being made to improve the observational efficiency and SNR through the introduction of data science methods such as GoDec and frequency-modulated local oscillators (FMLO) (Taniguchi et al. 2021; Taniguchi et al. 2020; Zhou & Tao 2011).

These updates are expected to contribute not only to the detection of faint prebiotic molecules and COMs but also to the detection of atomic line emissions from high- $z$  objects. In addition, the B4R and LMT, a single-dish telescope with a wide bandwidth, high frequency resolution, and high spatial resolution in the 2 mm band, have the potential to make significant contributions to unbiased survey observations. Observations of interstellar molecules, including COMs associated with protostars, have also been conducted in nearby low-mass star-forming regions. Detailed observations with ALMA have enabled studies that approach the issues of material transport and angular momentum transfer from protostellar envelopes to disks (e.g., Sakai et al. 2014). The factors behind the chemical diversity observed in astronomical objects during the course of star and planet formation are not yet fully understood, and it is essential to conduct survey observations of the environments surrounding protoplanetary disks using various tracer molecules. In addition, AGB stars, for which a large number of samples have been obtained through survey observations with infrared space telescopes (e.g., Spitzer; Blum et al. 2006), are known to be associated with dense molecular gas. Follow-up millimeter-wave survey observations targeting such dense molecular gas are also crucial for deepening our understanding of the chemical and physical environments of protoplanetary disks of high- and low-

**Fig. 7.** Comparison of  $X(\text{C}_2\text{H}_5\text{CN})$  and  $X(\text{CH}_3\text{OCHO})$  among other HMSFRs and the Orion-KL HC, CR. The triangle and inverted triangle represent  $X$  of the HC and CR in this study, respectively (see table 4). The circles show the eight sources observed by Coletta et al. (2020). The stars denote observations of Sgr B2(N1:SE1, N1:NW3, N2, N3, N4, N5) from Busch et al. (2024); Bonfand et al. (2017); Bonfand et al. (2019). The solid black line represents the correlation from Coletta et al. (2020), while the dashed black line represents the fitting results using the plots of the HC, CR (not assuming source size  $10''$ ) in this study, and Sgr B2(N) observed with a resolution  $S_{\text{beam}}$  below 0.1 pc (Bonfand et al. 2017; Bonfand et al. 2019; Busch et al. 2024; Sánchez-Monge et al. 2017). The color scale corresponds to  $S_{\text{beam}}$  [pc]. Alt text: The scatter plots and fitting results. The x axis is the relative abundance with respect to  $\text{H}_2$  of  $\text{CH}_3\text{OCHO}$  (methyl formate), and the y axis is the the relative abundance with respect to  $\text{H}_2$  of  $\text{C}_2\text{H}_5\text{CN}$  (ethyl cyanide, propionitrile).

mass stars that develop from the scale of molecular cloud cores and filaments, which include environments where AGB stars disperse carbon and nitrogen as stellar winds.

## 5 Conclusion

A 2 mm band SIS receiver, the B4R, was installed on the LMT-50 m atop the Sierra Negra Mountain in Mexico, at an altitude of 4600 m. This study analyzed the results of test observations conducted in November 2019 using the OTF observation technique, with a spatial resolution of  $11\text{--}12''$  and an observed area of  $5' \times 5'$ . The main findings are summarized as follows:

1. Emission lines from  $\text{H}35\alpha$ ,  $\text{H}51\gamma$  and 29 molecular species, including isotopologues, deuterated molecules, and vibrational states, were identified with a total bandwidth of 10 GHz using XCLASS (Möller et al. 2017). A total of 337 spectra were identified, and 49 spectra were labeled as unidentified. These detections and identifications were consistent with previous studies and confirmed the observational capabilities of spectral scans achieved by B4R/LMT-50 m. Concurrently, the difference in spectral intensity between N- and O-bearing COMs in the Orion-KL HC and CR regions has demonstrated the competitive spatial resolution achieved by the B4R optics within the LMT facility. In addition to the IRAM-30 m with the

2 mm band receiver Eight MIXER Receiver (EMIR) E150, the B4R/LMT-50 m offers wide bandwidth, high frequency resolution, and higher spatial resolution observations in the 2 mm band in the Northern Hemisphere.

2. We computed the maps of column density, rotational temperature, and relative abundance with respect to  $\text{H}_2$ , focusing on representative N- and O-bearing COMs, namely,  $\text{C}_2\text{H}_5\text{CN}$  and  $\text{CH}_3\text{OCHO}$ , by a rotation diagram using a two-dimensional method based on OTF observations using the B4R/LMT-50 m. The spatial distributions and values of the column density and rotational temperature were consistent with previous studies.
3. We compared  $X(\text{C}_2\text{H}_5\text{CN})$  and  $X(\text{CH}_3\text{OCHO})$  ( $v = 0$ ) in Orion-KL, our targeted observation region, with previously reported HMSFRs. The abundance ( $X$ ) was found to be dependent on the spatial scale of the source and, therefore, very sensitive to the angular resolution ( $S_{\text{beam}}$ ). This was confirmed by comparing  $\text{CH}_3\text{OCHO}$  (O-bearing COMs), which are more widely distributed and highly abundant, and  $\text{C}_2\text{H}_5\text{CN}$  (N-bearing COMs), which are relatively compactly distributed and could dominate central core observations. This suggests that the good correlation between  $X(\text{C}_2\text{H}_5\text{CN})$  and  $X(\text{CH}_3\text{OCHO})$  reported in a previous study (Coletta et al. 2020) may be affected by the extent to which the spatial scale of such angular resolution includes each molecular distribution with different

spatial coverages due to differences in the physical and chemical environments.

## Acknowledgments

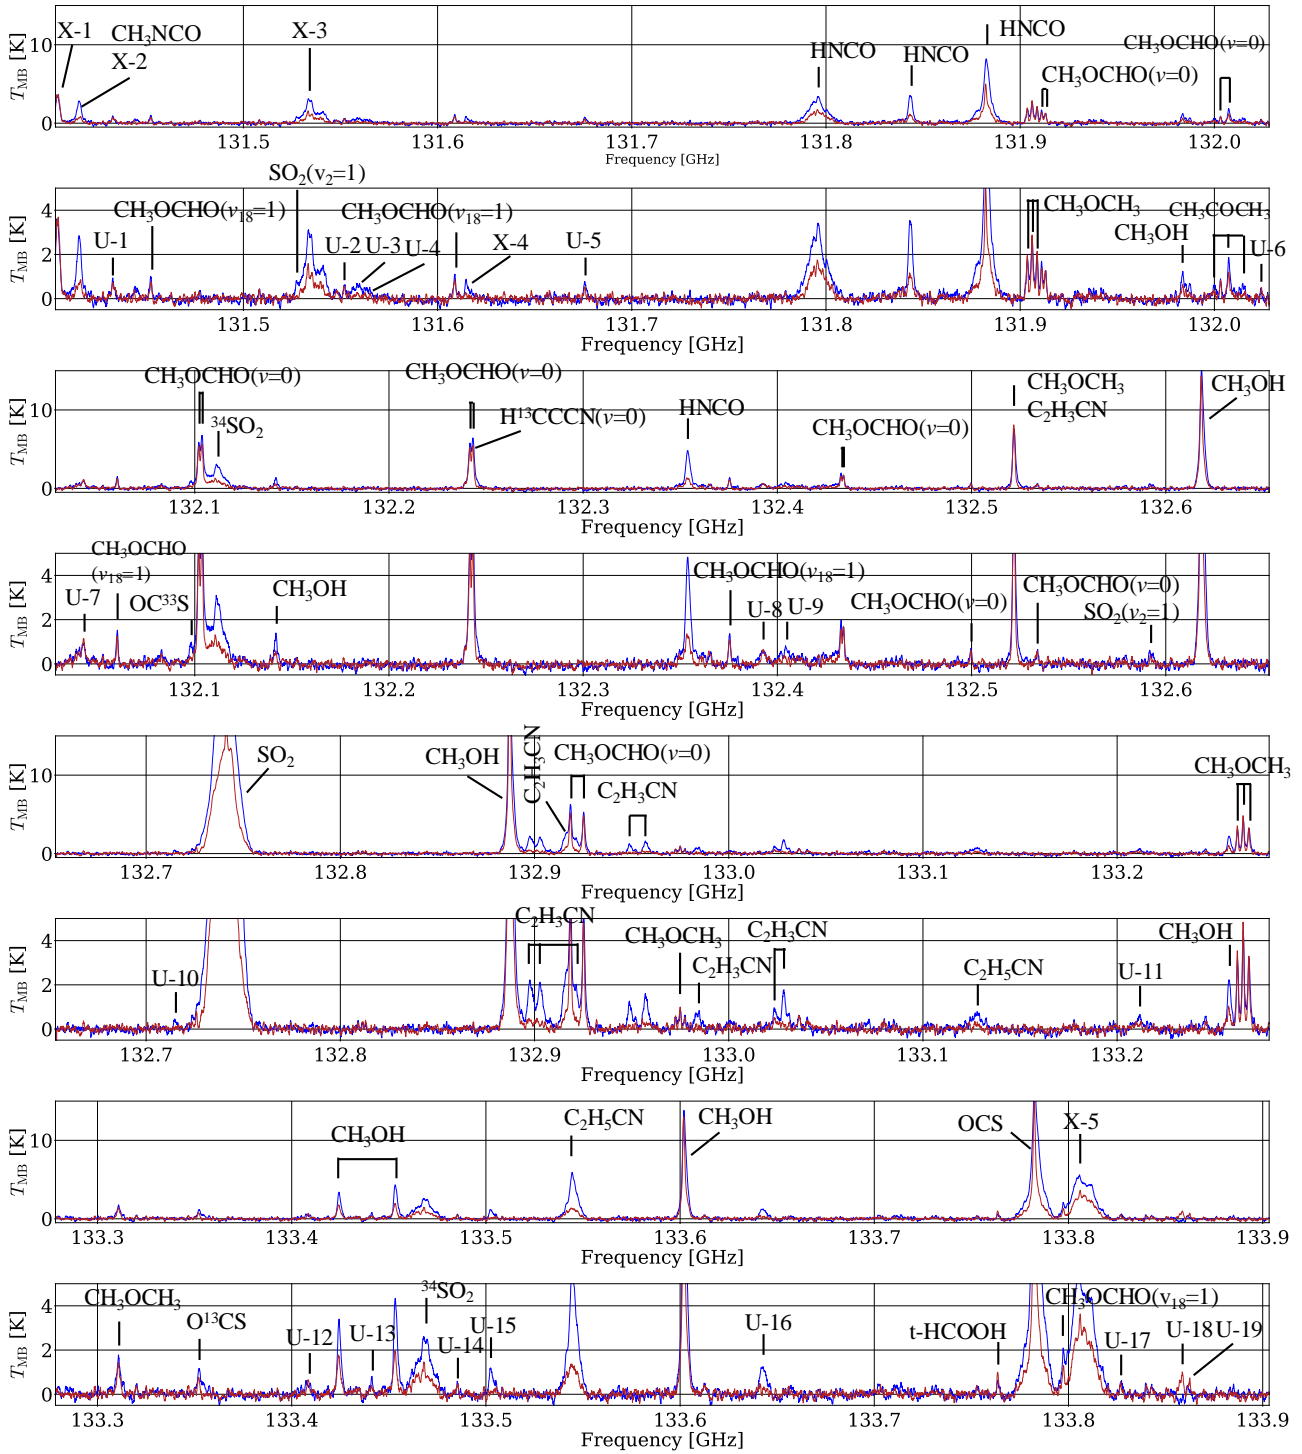

This work was financially supported by JSPS KAKENHI grant Numbers, JP15H02073, 17H06130 (RK, YT, KK), JP19K14754 (TT), 22H04939 (TS, KT, AT, YT, KK), JP19K21885, and JP25K01060 (HM). TY is supported by JSPS KAKENHI grant No. JP22J22889 and JP22KJ2625. KT is supported by JSPS KAKENHI Grant Numbers 20K14523 and 24K17096. TT is supported by MEXT Leading Initiative for Excellent Young Researchers Grant Number JPMXS0320200188. This paper makes use of data taken by the Large Millimeter Telescope Alfonso Serrano (LMT) in Mexico. The LMT project is a joint effort of the Instituto Nacional de Astrófisica, Óptica, y Electrónica (INAOE) and the University of Massachusetts at Amherst (UMASS). We also appreciate the support of the technical staff and the support scientists of the LMT during the commissioning campaign of the B4R. We would like to thank Editage (www.editage.jp) for English language editing.

## Appendix 1 Details of observed spectra

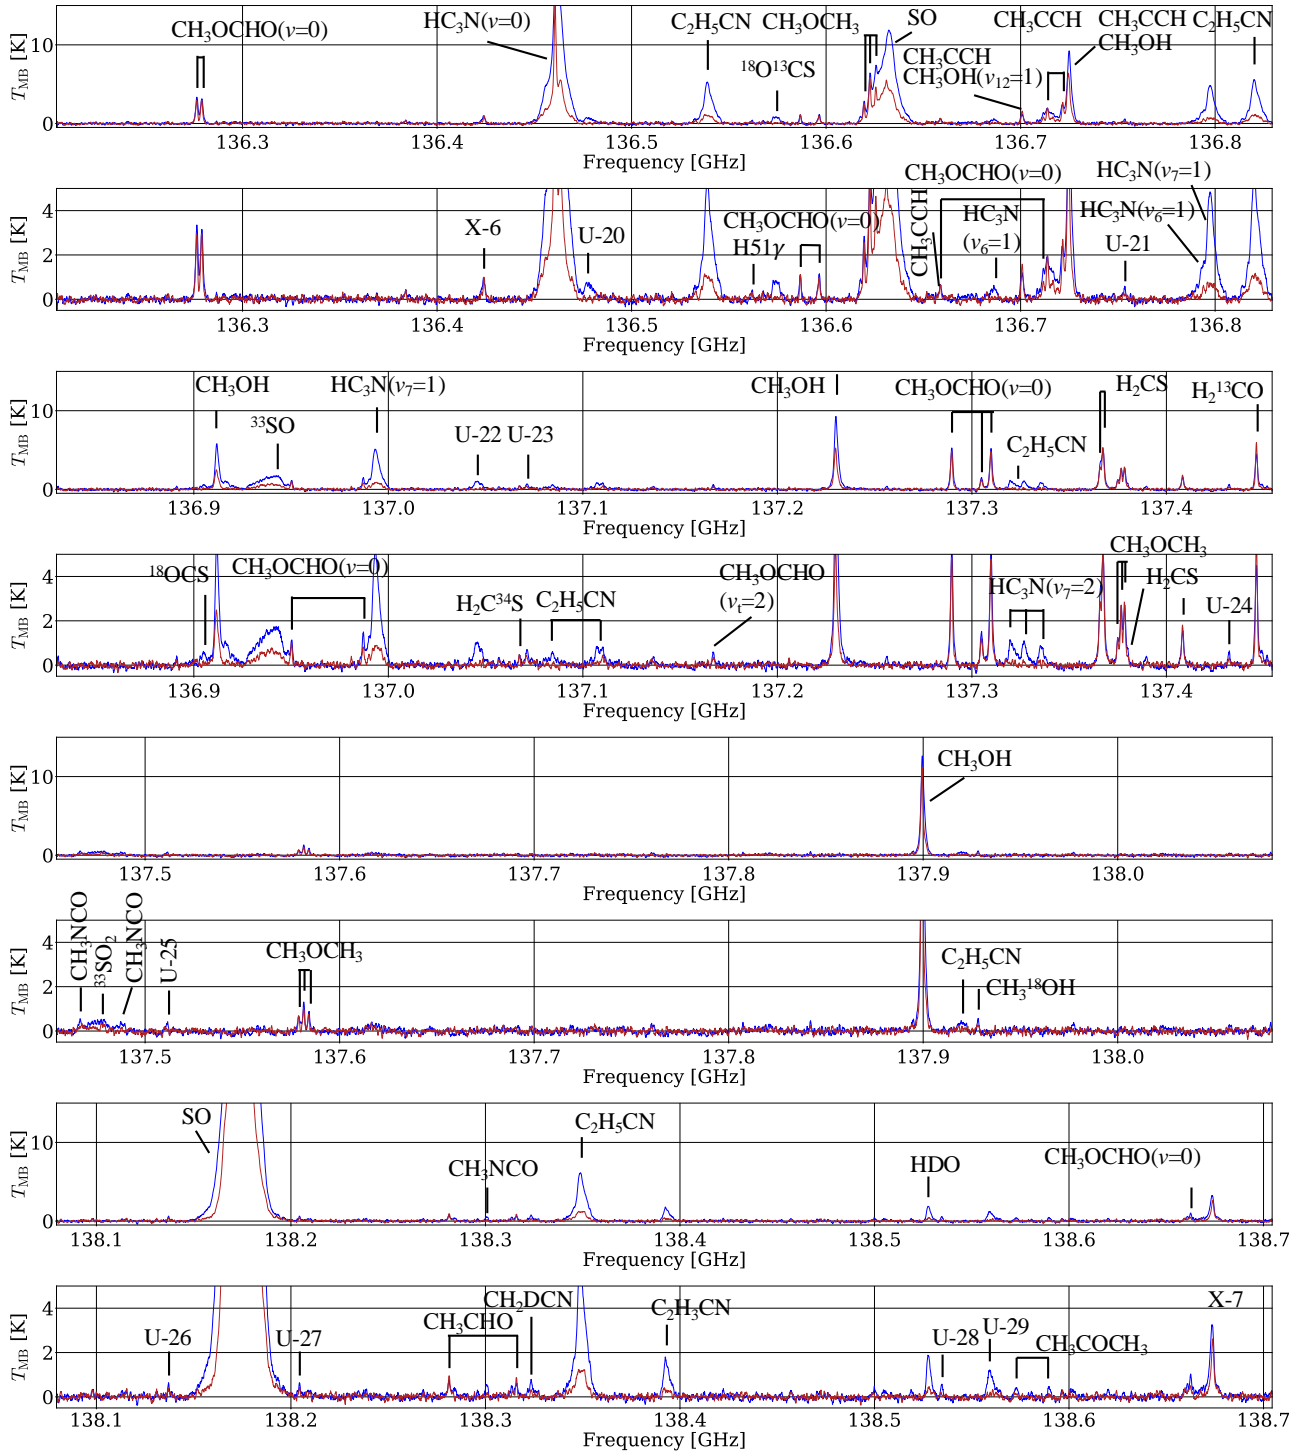

This section provides additional details of the observed spectra, as Section 3.1 outlines. The spectra within the frequency bands of 131.4–133.9 GHz, 136.2–138.7 GHz, 145.1–147.6 GHz, and 149.9–152.4 GHz, are shown in figures 8–11. Among the 404 lines detected, molecular names are assigned to 337 of the identified and tentatively identified lines, with the identified lines listed in table 6 and the tentatively identified lines listed in table 7. Tables 6 and 7 present the observed frequency (Obs. freq.),  $V_{\text{LSR}}$ , and  $T_a$  obtained from the peak tops, with values provided for both the HC and CR spectra (HC/CR). The line widths were determined by fitting using CASSIS (Vastel et al. 2015). When fitting with multiple components was appropriate, the widths of each component were listed together. The transition information and rest frequency (Rest. freq.) predominantly relied on the JPL values sourced from Splatalogue, whereas data exclusively available in the CDMS was obtained from the CDMS. The transition information and rest frequency (Rest. freq.) of recombination lines was obtained from Splatalogue. The 18 X-lines are indicated as (X-1)–(X-18) in figures 8–11, with details about the candidate molecules summarized in table 8. Lines resulting from the second downconversion or aliasing from the ADC and image sideband leakage are labeled as DC, ADC, and Image in table 8, respectively. The 49 U-lines are indicated by (U-1)–(U-49) in figures 8–11 and are listed in table 9. The observed frequency (Obs. freq.) is obtained from the peak tops, with values provided for both the HC and CR spectra (HC/CR) in tables 8 and 9. As with tables 6 and 7, the transition information and rest frequency (Rest. freq.) listed in table 8 are sourced from the JPL and CDMS catalogues. The values of  $T_a$  and the line widths in table 9 were obtained using the same method as described for tables 6 and 7.
