

On strong sharp phase transition in the random connection model

MIKHAIL CHEBUNIN* and Günter Last†

December 2, 2025

Abstract

We consider a random connection model (RCM) ξ driven by a Poisson process η . We derive exponential moment bounds for an arbitrary cluster, provided that the intensity t of η is below a certain critical intensity t_T . The associated subcritical regime is characterized by a finite mean cluster size, uniformly in space. Under an exponential decay assumption on the connection function, we also show that the cluster diameters are exponentially small as well. In the important stationary marked case and under a uniform moment bound on the connection function, we show that t_T coincides with t_c , the largest t for which ξ does not percolate. In this case, we also derive some percolation mean field bounds. These findings generalize some of the main results in [3]. Even in the classical unmarked case, our results are more general than what has been previously known. Our proofs are partially based on some stochastic monotonicity properties, which might be of interest in their own right.

Keywords: Random connection model, Poisson process, percolation, sharp phase transition, mean field lower bound, stochastic monotonicity.

1 Introduction

Let (\mathbb{X}, d) be a complete separable metric space, denote its Borel- σ -field by \mathcal{X} , and let λ be a locally finite and diffuse measure on \mathbb{X} . Let $t \in \mathbb{R}_+ := [0, \infty)$ be an intensity parameter and let η be a Poisson process on \mathbb{X} with intensity measure $t\lambda$, defined over a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. We often write \mathbb{P}_t instead of \mathbb{P} and \mathbb{E}_t for the associated expectation operator.

Let $\varphi: \mathbb{X}^2 \rightarrow [0, 1]$ be a measurable and symmetric function satisfying

$$D_\varphi(x) := \int \varphi(x, y) \lambda(dy) < \infty, \quad \lambda\text{-a.e. } x \in \mathbb{X}. \quad (1.1)$$

We refer to φ as *connection function*. The *random connection model* (RCM) is the random graph ξ whose vertices are the points of η and where a pair of distinct points $x, y \in \eta$ forms an edge with probability $\varphi(x, y)$, independently for different pairs. In an Euclidean setting, the RCM was introduced in [34] (see [28] for a textbook treatment), while the general Poisson version was studied in [23]. The RCM is a fundamental and versatile example of a spatial random graph. Of particular interest is the *stationary marked* case, where φ is translation invariant in the spatial coordinate. Special cases are the Boolean model (see [25, 36]) with general compact grains and the so-called weighted RCM; see [2, 3, 8, 14, 15, 19, 26, 35].

Following common terminology of percolation theory, we refer to a component of ξ as *cluster*. The RCM ξ *percolates*, if it has an infinite cluster, that is a component with infinitely many vertices. Generalizing many earlier results, it was shown in [4] that the stationary marked RCM can have at most one infinite cluster, provided a natural irreducibility assumption holds. Under suitable integrability assumptions on the connection function φ , we establish exponential moment properties for the size and diameter of a

cluster in the subcritical regime $t < t_T$, where t_T is defined by (1.3). Again, under an integrability assumption, we prove that the stationary marked RCM undergoes a strong sharp phase transition at the critical intensity t_c , defined by (1.2). We also provide lower bounds for two critical exponents. Our method of proving the strong sharpness of the phase transition will be based on transferring some of the beautiful ideas from the seminal paper [1] in a way similar to [3].

In the following, we outline some of our main results. Take $v \in \mathbb{X}$ and add independent connections between v and the points from η . Let C^v denote the component of v in this augmentation of ξ . The first critical intensity is defined by

$$t_c := \sup\{t \geq 0 : \mathbb{P}_t(|C^v| < \infty) = 0 \text{ for } \lambda\text{-a.e. } v\}, \quad (1.2)$$

where $|C^v|$ stands for the number of vertices of C^v . The second is defined by

$$t_T := \sup\{t \geq 0 : \text{ess sup}_{v \in \mathbb{X}} \mathbb{E}_t |C^v| < \infty\}, \quad (1.3)$$

where the essential supremum refers to λ . It is clear that $t_T \leq t_c$. We will show in Lemma 6.1 that $t_T > 0$ if and only if

$$D_\varphi^* := \text{ess sup}_{v \in \mathbb{X}} D_\varphi(v) < \infty \quad (1.4)$$

and that $t_T \geq (D_\varphi^*)^{-1}$. The following result is the content of our Theorem 6.10.

Theorem 1.1. *For $t < t_T$ there exists $\delta_1 \equiv \delta_1(t)$ such that $\text{ess sup}_{v \in \mathbb{X}} \mathbb{E}_t e^{\delta_1 |C^v|} < \infty$.*

An important special case of a RCM is the stationary marked RCM. In that case η is a Poisson process on $\mathbb{X} := \mathbb{R}^d \times \mathbb{M}$ with intensity measure $t\lambda_d \otimes \mathbb{Q}$, where \mathbb{M} is a complete separable metric space, λ_d denotes Lebesgue measure on \mathbb{R}^d and \mathbb{Q} is a probability measure on \mathbb{M} . The connection function φ is assumed to be translation invariant in the sense of (4.2). In the *unmarked case* $|\mathbb{M}| = 1$ it was proved in [27] that $t_T = t_c$, provided that the (in a sense) minimal integrability assumption $\int \varphi(0, x) dx < \infty$ is satisfied and assuming that $\varphi(0, x)$ is a non-increasing function of the Euclidean norm of x . This is a weak version of a sharp phase transition. It was shown in [22] that the cluster size has an exponential tail, provided the connection function has a bounded support. Afterwards, this strong sharp phase transition was derived in [17] for an isotropic (and monotone) connection function with possibly unbounded support. Even in this very special case of an (unmarked) stationary RCM, Theorem 1.1 extends all these results without making any assumption other than the integrability of φ . In the marked case, the situation is considerably more complicated. To state a second main result of our paper, we define $d_\varphi(p, q) := \int \varphi((0, p), (x, q)) dx$ for $p, q \in \mathbb{M}$. Our Theorem 8.2 (and Remark 8.11) shows the following. To avoid trivialities, we assume that $\int d_\varphi(p, q) \mathbb{Q}^2(d(p, q)) > 0$.

Theorem 1.2. *Suppose that ξ is a stationary marked random connection model and assume that*

$$\text{ess sup}_{p \in \mathbb{M}} \int d_\varphi(p, q)^2 \mathbb{Q}(dq) < \infty, \quad (1.5)$$

where the essential supremum refers to \mathbb{Q} . Then $t_T = t_c \in (0, \infty)$ and $\int \mathbb{E}_{t_c} |C^{(0, p)}| \mathbb{Q}(dp) = \infty$.

Note that (1.5) is (slightly) stronger than (1.4), implicitly assumed in Theorem 1.1. Under the uniform moment assumption (1.5), Theorems 1.1 and 1.2 imply a strong sharp phase transition at $t_c = t_T$. For the Boolean model with (deterministically) bounded grains (covered by Theorems 1.1 and 1.2) it was proved in [37] that the size of a typical cluster is exponentially small for $t < t_c$. This is a continuum analogue of classical results in [30] and [1]; see also [10] for a new and elegant proof (that inspired [37] and [22]). Using a continuum version of the OSSS-inequality the result from [37] was extended in [24] so as to cover the

so-called k -percolation. Theorem 1.2 generalizes [3, Corollary 1.10] by proving a sharp phase transition under a weaker integrability assumption on the connectivity function and without assuming any kind of irreducibility.

Condition (1.5) fails for a spherical Boolean model with a radius distribution of unbounded support; see Example 4.3. To get from (1.5) to weaker conditions for a sharp phase transition at t_c , remains a challenging problem. In the case of the spherical Boolean model, an important step was made in [11], treating an unbounded radius distribution with a finite d -th moment. In this case $t_c > 0$ while $t_T = 0$ (see also Example 4.3). Nevertheless, it is proved there in the subcritical regime that under the polynomial (resp. exponential) decay behavior of the tail of the radius distribution, certain connection probabilities show a similar behavior. Using an approach from [12, 13] it was shown in [5] that even for Pareto distributed radii (with minimal moment assumption) the model undergoes such a *subcritical sharpness*. Related results for the *soft Boolean model* with Pareto distributed weights (a special case of Example 4.4) can be found in [18].

The paper is organized as follows. In Section 2 we give the formal definition of the RCM ξ and introduce the notation used throughout the paper. Section 3 presents the RCM version of the multivariate Mecke equation, while Section 4 introduces some basic notation and concepts of percolation theory. Section 5 presents a spatial Markov property (taken from [4]) and some results on stochastic ordering. Section 6 provides a criterion for subcriticality and for exponential moments of cluster sizes, while Section 7 deals with cluster diameters. In Section 8 we discuss the stationary marked RCM, with Theorem 8.2 summarizing our main results. Proposition 8.15 presents a mean field lower bound for mean cluster sizes in the subcritical case, while Theorem 8.21 provides such a bound for percolation probabilities in the supercritical case.

2 Formal definition of the RCM

To define a RCM we follow [4]. Let \mathbf{N} ($\mathbf{N}_{<\infty}$) denote the space of all simple locally finite (finite) counting measures on \mathbb{X} , equipped with the standard σ -field, see e.g. [25]. A measure $\nu \in \mathbf{N}$ is identified with its support $\{x \in \mathbb{X} : \nu(\{x\}) = 1\}$ and describes the set of vertices of a (deterministic) graph. If $\nu(\{x\}) = 1$ we write $x \in \nu$. Any $\nu \in \mathbf{N}$ can be written as a finite or infinite sum $\nu = \delta_{x_1} + \delta_{x_2} + \dots$ of Dirac measures, where the x_i are pairwise distinct and do not accumulate in bounded sets. The space of (undirected) graphs with vertices from \mathbb{X} (and no loops) is described by the set \mathbf{G} of all counting measures μ on $\mathbb{X} \times \mathbf{N}$ with the following properties. First, we assume that the measure $V(\mu) := \mu(\cdot \times \mathbf{N})$ is locally finite and simple, that is, an element of \mathbf{N} . We write $x \in \mu$ if $x \in V(\mu)$ (that is $\mu(\{x\} \times \mathbf{N}) = 1$). In this case, there is a unique $\psi_x \in \mathbf{N}$ such that $(x, \psi_x) \in \mu$. We assume that $x \notin \psi_x$. Finally, if $x \in V(\mu)$ and $y \in \psi_x$ then we assume that $(y, \psi_y) \in \mu$ and $x \in \psi_y$. Also, \mathbf{G} is equipped with the standard σ -field. There is an edge between $x, y \in V(\mu)$ if $y \in \psi_x$ (and hence $x \in \psi_y$). If $\psi_x = 0$, then x is *isolated*.

We write $|\mu| := \mu(\mathbb{X} \times \mathbf{N})$ for the cardinality of $\mu \in \mathbf{G}$ and similarly for $\nu \in \mathbf{N}$. Hence $|\mu| = |V(\mu)|$. For $x, y \in V(\mu)$ we write $x \sim y$ (in μ) if there is an edge between x and y and $x \leftrightarrow y$ (in μ) if there is a path in μ leading from x to y . For $A \subset \mathbb{X}$ we write $x \sim A$ (in μ) if there exists $y \in A \cap V(\mu)$ such that $x \sim y$. Let $\mu, \mu' \in \mathbf{G}$. Then μ is a *subgraph* of μ' if $V(\mu) \leq V(\mu')$ (as measures) and for each $(x, \psi) \in \mu$ and $(x, \psi') \in \mu'$ we have $\psi \leq \psi'$. Note that this is not the same as $\mu \leq \mu'$.

Let χ be a simple point process on \mathbb{X} , which is a random element of \mathbf{N} . The reader should think of a Poisson process possibly augmented by additional (deterministic) points. By [25, Proposition 6.2] there exist random elements X_1, X_2, \dots of \mathbb{X} such that $\chi = \sum_{n=1}^{|\chi|} \delta_{X_n}$, where $X_m \neq X_n$ whenever $m \neq n$ and $m, n \leq |\chi|$. Let $(Z_{m,n})_{m,n \in \mathbb{N}}$ be a double sequence of random elements uniformly distributed on $[0, 1]$ such that $Z_{m,n} = Z_{n,m}$ for all $m, n \in \mathbb{N}$ and such that $Z_{m,n}$, $m < n$, are independent. Then the RCM (based

on χ) is the point process

$$\xi := \sum_{m=1}^{|\chi|} \delta_{(X_m, \Psi_m)},$$

where

$$\Psi_m := \sum_{n=1}^{|\chi|} \mathbf{1}\{n \neq m, Z_{m,n} \leq \varphi(X_m, X_n)\} \delta_{X_n}.$$

While the definition of ξ depends on the ordering of the points of χ , its distribution does not.

We now introduce some notation used throughout the paper. For $\mu, \mu' \in \mathbf{G}$, we often interpret $\mu + \mu'$ as the measure in \mathbf{G} with the same support as $\mu + \mu'$. A similar convention applies to $\nu, \nu' \in \mathbf{N}$. Let $\mu \in \mathbf{G}$. For $B \in \mathcal{X}$ we write $\mu(B) := \mu(B \times \mathbf{N})$. More generally, given a measurable function $f: \mathbb{X} \rightarrow \mathbb{R}$ we write $\int f(x) \mu(dx) := \int f(x) \mu(dx \times \mathbf{N})$. In the same spirit, we write $g(\mu) := g(V(\mu))$, whenever g is a mapping on \mathbf{N} . These (slightly abusing) conventions lighten the notation and should not cause any confusion. For $B \in \mathcal{X}$ we denote by $\mu[B] \in \mathbf{G}$ the *restriction* of μ to B , that is the graph with vertex set $V(\mu) \cap B$ which keeps only those edges from μ with both end points from B . In the same way, we use the notation $\mu[\nu]$ for $\nu \in \mathbf{N}$. Similarly, for a measure ν on \mathbb{X} (for instance for $\nu \in \mathbf{N}$) we denote by $\nu_B := \nu(B \cap \cdot)$ the restriction of ν to a set $B \in \mathcal{X}$. Assume now that μ is a subgraph of μ' . For $n \in \mathbb{N}_0$ let $C_n^\mu(\mu') \in \mathbf{G}$ denote the restriction of μ' to those $v \in V(\mu')$ with $d_{\mu'}(v, \mu) = n$, where $d_{\mu'}$ denotes the distance within the graph μ' . Note that $C_0^\mu(\mu')$ is just the graph μ . Slightly abusing our notation, we write $C_0^\mu(\mu') = \mu$ and $V_n^\mu(\mu') = V(C_n^\mu(\mu'))$. For $v \notin V(\mu')$ we set $C^v(\mu') := 0$, interpreted as an empty graph (a graph without vertices). The cluster $C^\mu(\mu')$ of μ in μ' is the graph μ' restricted to

$$V^\mu(\mu') = \sum_{n=0}^{\infty} V_n^\mu(\mu'),$$

while $C_{\leq n}^\mu(\mu')$, $n \in \mathbb{N}_0$, is the graph μ' restricted to $V_0^\mu(\mu') + \dots + V_n^\mu(\mu')$. For later purposes, it will be convenient to define $C_{\leq -1}^\mu(\mu') = C_{-1}^\mu(\mu') := 0$ as the zero measure. Throughout we write $V_n^{V(\mu)}(\mu') := V_n^\mu(\mu')$ and $V_n^\mu(\mu', \cdot) := V_n^\mu(\mu')(\cdot)$, $n \in \mathbb{N}_0$, and similarly for $V_{\leq n}^\mu$ and V^μ . We also often refer to $C^v(\mu')$ as the *cluster* of v in μ' for $v \in V(\mu')$.

Given an RCM based on a Poisson process η on \mathbb{X} with diffuse intensity measure λ , we use the following notation. For $v \in \mathbb{X}$ and $n \in \mathbb{N}_0$ we set

$$C^v := C^v(\xi^v), \quad V^v := V^v(\xi^v), \quad C_n^v := C_n^v(\xi^v), \quad V_n^v := V_n^v(\xi^v), \quad C_{\leq n}^v := C_{\leq n}^v(\xi^v), \quad V_{\leq n}^v := V_{\leq n}^v(\xi^v),$$

or $C_\lambda^v, V_\lambda^v, C_{n,\lambda}^v, V_{n,\lambda}^v, C_{\leq n,\lambda}^v$ and $V_{\leq n,\lambda}^v$, if we need to emphasize the dependence on λ . Moreover, we write $V_{\leq n}^{v!} := V_{\leq n}^v - \delta_v$ and similarly for V^v .

3 The Mecke equation

Let ξ be a RCM based on a Poisson process η on \mathbb{X} with diffuse intensity measure λ . Our first crucial tool is a version of the Mecke equation (see [25, Chapter 4]) for ξ . Given $n \in \mathbb{N}$ and $\mathbf{x}_n := (x_1, \dots, x_n) \in \mathbb{X}^n$ we denote $\delta_{\mathbf{x}_n} := \delta_{x_1} + \dots + \delta_{x_n}$ and $\eta^{\mathbf{x}_n} := \eta + \delta_{\mathbf{x}_n}$ (removing possible multiplicities) and let $\xi^{\mathbf{x}_n}$ denote a RCM based on $\eta^{\mathbf{x}_n}$. It is useful to construct $\xi^{\mathbf{x}_n}$ in a specific way as follows. We connect x_1 with the points in η using independent connection decisions which are independent of ξ . We then proceed inductively, finally connecting x_n to $\eta + \delta_{\mathbf{x}_{n-1}}$. For a measurable function $f: \mathbb{X}^n \times \mathbf{G} \rightarrow [0, \infty]$ the Mecke equation for ξ states that

$$\mathbb{E} \int f(\mathbf{x}_n, \xi) \eta^{(n)}(d\mathbf{x}_n) = \mathbb{E} \int f(\mathbf{x}_n, \xi^{\mathbf{x}_n}) \lambda^n(d\mathbf{x}_n), \quad (3.1)$$

where integration with respect to the *factorial measure* $\eta^{(n)}$ of η means summation over all n -tuples of pairwise distinct points from η .

For given $v \in \mathbb{X}$ and $\mathbf{x}_n \in \mathbb{X}^n$ we denote $(v, \mathbf{x}_n) := (v, x_1, \dots, x_n) \in \mathbb{X}^{n+1}$. We sometimes use (3.1) in the form

$$\mathbb{E} \int f(\mathbf{x}_n, \xi^v) \eta^{(n)}(d\mathbf{x}_n) = \mathbb{E} \int f(\mathbf{x}_n, \xi^{v, \mathbf{x}_n}) \lambda^n(d\mathbf{x}_n). \quad (3.2)$$

The proofs of (3.1) and (3.2) can be found in [4].

4 Percolation and critical intensities

4.1 Notation and terminology in the general case

Let $t \geq 0$ be an intensity parameter and let ξ be a RCM based on a Poisson process η on \mathbb{X} with an intensity measure $t\lambda$, where λ is a locally finite and diffuse measure on \mathbb{X} . The RCM ξ *percolates* if it has an infinite cluster, a component with infinitely many vertices. We also say that the RCM (or t) is *subcritical* if all clusters have only a finite number of points, that is,

$$\mathbb{P}_t(|V^v| < \infty) = 1, \quad \lambda\text{-a.e. } v \in \mathbb{X}.$$

In accordance with (1.2) we define the *critical intensity* t_c as the supremum of all $t \in \mathbb{R}_+$ such that above holds. A standard coupling argument shows that ξ is subcritical for all $t < t_c$.

Let $v \in \mathbb{X}$, $t \geq 0$ and $n \in \mathbb{N}_0$. Mean generations and cluster sizes are denoted by

$$c_n^v(t) := \mathbb{E}_t|V_n^v|, \quad c_{\leq n}^v(t) := \mathbb{E}_t|V_{\leq n}^v|, \quad c^v(t) := \mathbb{E}_t|V^v|.$$

It is clear that $c_1^v(t) = tD_\varphi(v)$ and

$$c^v(t) = \sum_{n=0}^{\infty} c_n^v(t) = \lim_{n \rightarrow \infty} c_{\leq n}^v(t).$$

For a measurable function $L: \mathbb{X} \rightarrow \mathbb{R} \cup \{\pm\infty\}$ we define the ∞ -norm by $\|L\|_\infty := \text{ess sup}_{v \in \mathbb{X}} |L(v)|$, where the essential supremum refers to λ . We abbreviate

$$D_\varphi^* := \|D_\varphi\|_\infty, \quad c_n^*(t) := \|c_n(t)\|_\infty, \quad c_{\leq n}^*(t) := \|c_{\leq n}(t)\|_\infty, \quad c^*(t) := \|c(t)\|_\infty. \quad (4.1)$$

The *second critical intensity* t_T is defined as the supremum of all $t \in \mathbb{R}_+$ such that $c^*(t) < \infty$. It is clear that $t_T \leq t_c$.

4.2 The stationary marked RCM

In this subsection, we consider the important special case of a stationary RCM; see e.g. [3, 8, 4]. Let \mathbb{M} be a complete separable metric space (the mark space) equipped with a probability measure \mathbb{Q} (the mark distribution). Set $\mathbb{X} := \mathbb{R}^d \times \mathbb{M}$ be equipped with the product of the Borel σ -field $\mathcal{B}(\mathbb{R}^d)$ on \mathbb{R}^d and the Borel σ -field on \mathbb{M} . We assume that $\lambda = \lambda_d \otimes \mathbb{Q}$, where λ_d denotes the Lebesgue measure on \mathbb{R}^d . If $(x, p) \in \mathbb{X}$ then we call x location of (x, p) and p the mark of x . Instead of \mathbf{N} we consider the (smaller set) $\mathbf{N}(\mathbb{X})$ of all counting measures χ on \mathbb{X} such that $\chi(\cdot \times \mathbb{M})$ is locally finite (w.r.t. the Euclidean metric) and simple. We can and will assume that the Poisson process η is a random element of $\mathbf{N}(\mathbb{X})$.

The symmetric connection function $\varphi: (\mathbb{R}^d \times \mathbb{M})^2 \rightarrow [0, 1]$ is assumed to satisfy

$$\varphi((x, p), (y, q)) = \varphi((0, p), (y - x, q)). \quad (4.2)$$

This allows us to write $\varphi(x, p, q) := \varphi((0, p), (x, q))$, where 0 denotes the origin in \mathbb{R}^d . The RCM ξ is *stationary* in the sense that $T_x \xi \stackrel{d}{=} \xi$, $x \in \mathbb{R}^d$, where for $\mu \in \mathbf{G}$, the measure $T_x \mu$ is (shift of μ by x) defined by $T_x \mu := \int \mathbf{1}\{(y - x, q, \nu) \in \cdot\} \mu(d(y, q, \nu))$. It is also ergodic; see [4].

Remark 4.1. The argument in [4] can be extended to yield that $T_x \xi^{(x,p)} \stackrel{d}{=} \xi^{(0,p)}$ for $\lambda_d \otimes \mathbb{Q}$ -a.e. $(x, p) \in \mathbb{R}^d \times \mathbb{M}$. Hence, if $f: \mathbf{G} \rightarrow \mathbb{R}$ is measurable and shift invariant, then $f(\xi^{(x,p)}) \stackrel{d}{=} f(\xi^{(0,p)})$ for $\lambda_d \otimes \mathbb{Q}$ -a.e. $(x, p) \in \mathbb{R}^d \times \mathbb{M}$. Therefore, the definitions (1.2) and (1.3) of t_c and t_T can be simplified. For instance, we have

$$t_c = \sup\{t \geq 0 : \mathbb{P}_t(|C^{(0,p)}| < \infty) = 0 \text{ for } \mathbb{Q}\text{-a.e. } p\}. \quad (4.3)$$

The function D_φ (defined by (1.1)) takes the form

$$D_\varphi((x, p)) = \iint \varphi(y, p, q) dy \mathbb{Q}(dq), \quad (x, p) \in \mathbb{R}^d \times \mathbb{M},$$

while D_φ^* is given by

$$\operatorname{ess\,sup}_{p \in \mathbb{M}} \iint \varphi(y, p, q) dy \mathbb{Q}(dq),$$

where the essential supremum now refers to \mathbb{Q} . Similar comments apply to other characteristics introduced in Subsection 4.1. For instance, we have $c^*(t) = \operatorname{ess\,sup}_{p \in \mathbb{M}} c^{(0,p)}(t)$. We often write

$$\bar{c}_n(t) := \int c_n^{(0,p)}(t) \mathbb{Q}(dp), \quad \bar{c}_{\leq n}(t) := \int c_n^{(0,p)}(t) \mathbb{Q}(dp), \quad \bar{c}(t) := \int c^{(0,p)}(t) \mathbb{Q}(dp). \quad (4.4)$$

It is convenient to introduce a random element Q_0 of \mathbb{M} which is independent of ξ , and has distribution \mathbb{Q} . Then we denote by C^{Q_0} the cluster of $(0, Q_0)$ in the RCM ξ^{Q_0} arising from ξ by adding independent connections between $(0, Q_0)$ and the points from η . This is the cluster of a *typical vertex* and we let V^{Q_0} denote its vertex set. Then we can write $\bar{c}(t) = \mathbb{E}_t[|V^{Q_0}|]$ and similar for other quantities.

Define

$$\theta^p(t) := \mathbb{P}_t(|C^{(0,p)}| = \infty), \quad t \geq 0, \quad p \in \mathbb{M},$$

as the probability that the cluster of a vertex $(0, p) \in \mathbb{X}$ has infinite size. In the following, we use the $L^r(\mathbb{Q})$ -norms to determine the size of functions. For each $r \in [1, +\infty]$, we define the critical intensities

$$t_c^{(r)} := \inf\{t \geq 0 : \|\theta(t)\|_r > 0\}, \quad (4.5)$$

$$t_T^{(r)} := \inf\{t \geq 0 : \|c(t)\|_r = \infty\}. \quad (4.6)$$

It is clear that $t_c^{(r)}$ is r -independent, since it only matters if $\theta^p(t) = 0$ for \mathbb{Q} -a.e. $p \in \mathbb{M}$ or not. Therefore, all the critical intensities $t_c^{(r)}$ coincide with the first critical intensity t_c , which we defined for a general RCM. Note that $t_T^{(r)} \leq t_c$ for all r . Moreover, $t_T^{(\infty)}$ coincides with the second critical intensity t_T , which we have also defined for a general RCM. From Jensen's inequality, it is clear that $t_T^{(r)}$ is non-increasing in r . Therefore,

$$0 \leq t_T = t_T^{(\infty)} \leq t_T^{(r_2)} \leq t_T^{(r_1)} \leq t_T^{(1)} \leq t_c, \quad 1 \leq r_1 \leq r_2 \leq \infty. \quad (4.7)$$

Let

$$\bar{\theta}(t) := \|\theta(t)\|_1 = \int \theta^p(t) \mathbb{Q}(dp), \quad t \geq 0,$$

denote the percolation probability, that is, the probability that the cluster of a typical vertex is infinite. Let C_∞ be the set of all $\mu \in \mathbf{G}$ such that μ has an infinite cluster. It is easy to see that $\bar{\theta}(t) > 0$ iff $\mathbb{P}_t(\xi \in C_\infty) = 1$. In fact, if $t < t_c$ then $\mathbb{P}_t(\xi \in C_\infty) = 0$ and if $t > t_c$ then $\mathbb{P}_t(\xi \in C_\infty) = 1$. Under a natural irreducibility assumption, ξ can have at most one infinite cluster; see [4].

Remark 4.2. In the unmarked case ($|\mathbb{M}| = 1$) the connection function φ is just a function on \mathbb{R}^d . Under the minimal assumption $0 < \int \varphi(x) dx < \infty$ it was shown in [34] that $t_c \in (0, \infty)$.

The marked RCM is a very rich and flexible model of a spatial random graph. We refer to [3, 4, 15] for many examples. For further reference, we provide just two of them here.

Example 4.3. Assume that $\mathbb{M} = \mathbb{R}_+$ and $\varphi(x, p, q) = \mathbf{1}\{\|x\| \leq p + q\}$, where $\|x\|$ denotes the Euclidean norm of $x \in \mathbb{R}^d$. The RCM ξ is known as the spherical Boolean model or as *Gilbert graph* with radius distribution \mathbb{Q} ; see e.g. [25, Chapter 16] for more detail. We have that

$$D_\varphi((0, r)) = \kappa_d \int (r + s)^d \mathbb{Q}(ds), \quad r \geq 0, \quad (4.8)$$

where κ_d stands for the volume of the unit ball. Therefore our basic assumption (1.1) is equivalent with $\int r^d \mathbb{Q}(dr) < \infty$. This is the minimal assumption for having a reasonable model. Under the additional assumption $\mathbb{Q}\{0\} < 1$ it was proved in [12, 16] that $t_c \in (0, \infty)$. On the other hand, if \mathbb{Q} has unbounded support, then $D_\varphi^* = \infty$ and $t_T = 0$; see Lemma 6.1.

Example 4.4. Assume that $\mathbb{M} = (0, 1)$ equipped with Lebesgue measure \mathbb{Q} . Assume that

$$\varphi((x, p), (y, q)) = \rho(g(p, q)\|x - y\|^d),$$

for a profile function $\rho: [0, \infty) \rightarrow [0, 1]$ and a kernel function $g: (0, 1) \times (0, 1) \rightarrow [0, \infty)$. We assume that $m_\rho := \int \rho(\|x\|^d) dx$ is positive and finite. This model was studied in [15] under the name *weight-dependent random connection model*, for decreasing profile function and increasing kernel function. Then

$$\iint \varphi(x, p, q) dx dq = m_\rho \int g(p, q)^{-1} dq,$$

and (1.1) holds if $g(p, \cdot)^{-1}$ is integrable for each $p \in (0, 1)$. This is the case in all examples studied in [15], where it is also asserted that $t_c < \infty$. Sufficient conditions for $t_c \in (0, \infty)$ can also be found in [3, 6].

5 A spatial Markov property and stochastic ordering

We consider a general RCM ξ based on a Poisson process η on \mathbb{X} with diffuse intensity measure λ . Given $\mu \in \mathbf{N}$, we denote the RCM based on $\eta + \mu$ by ξ^μ . We first recall the *spatial Markov property*, as formulated in [4].

Let ν be a locally finite and diffuse measure on \mathbb{X} . We often write Π_ν for the distribution of a Poisson process with intensity measure ν . We set $\bar{\varphi} := 1 - \varphi$ and define for $x \in \mathbb{X}$, $\nu \in \mathbf{N}$

$$\bar{\varphi}(\nu, x) := \prod_{y \in \nu} \bar{\varphi}(x, y), \quad \varphi(\nu, x) := 1 - \bar{\varphi}(\nu, x), \quad \varphi_\lambda(\nu) := \int \varphi(\nu, x) \lambda(dx). \quad (5.1)$$

We recall our general convention $\varphi(\mu, x) := \varphi(V(\mu), x)$ and $\varphi_\lambda(\mu) := \varphi_\lambda(V(\mu))$ for $\mu \in \mathbf{G}$. Next we define two kernels from \mathbf{N} to \mathbb{X} and from $\mathbf{N} \times \mathbf{N}$ to \mathbb{X} (using the same notation K_ν for simplicity), by

$$K_\nu(\mu, dx) := \bar{\varphi}(\mu, x) \nu(dx), \quad K_\nu(\mu, \mu', dx) := \bar{\varphi}(\mu, x) \varphi(\mu', x) \nu(dx). \quad (5.2)$$

Proposition 5.1 will provide an interpretation of this kernel. Denoting by 0 the zero measure, we note that

$$K_\nu(0, dx) = \nu(dx), \quad K_\nu(0, \mu', dx) = \varphi(\mu', x) \nu(dx), \quad K_\nu(\mu, 0, dx) = 0. \quad (5.3)$$

We write $K_\nu(\mu) := K_\nu(\mu, \cdot)$ and $K_\nu(\mu, \mu') := K_\nu(\mu, \mu', \cdot)$. Note that $K_\lambda(0, \mu, \mathbb{X}) = \varphi_\lambda(\mu)$; see (5.1).

The following spatial Markov property of the random graph ξ^ν was proved in [4].

Proposition 5.1. *The sequence $(V_{\leq n-1}^v, V_n^v)_{n \in \mathbb{N}_0}$ is a Markov process with transition kernel*

$$(\mu, \mu') \mapsto \int \mathbf{1}\{(\mu + \mu', \psi) \in \cdot\} \Pi_{K_\lambda(\mu, \mu')}(d\psi).$$

In the following, we often abbreviate $K := K_\lambda$. Given $n \in \mathbb{N}$ we define a probability kernel H_n from $\mathbf{N} \times \mathbf{N}$ to \mathbf{N} by

$$H_n(\mu, \mu', \cdot) := \int \cdots \int \mathbf{1}\{\psi_n \in \cdot\} \Pi_{K(\mu + \mu' + \psi_1 + \cdots + \psi_{n-2}, \psi_{n-1})}(d\psi_n) \cdots \Pi_{K(\mu + \mu', \psi_1)}(d\psi_2) \Pi_{K(\mu, \mu')}(d\psi_1). \quad (5.4)$$

The Proposition 5.1 implies that

$$\mathbb{P}(V_n^v \in \cdot) = H_n(0, \delta_v, \cdot), \quad v \in \mathbb{X}. \quad (5.5)$$

Corollary 5.2. *For λ -a.e. $v \in \mathbb{X}$ and $n \in \mathbb{N}_0$ under condition (1.1) we have $\mathbb{P}(|V_n^v| < \infty) = 1$.*

The following useful property of the kernel K_λ can be easily proved by induction.

Lemma 5.3. *Let $n \in \mathbb{N}$ and $\mu_0, \dots, \mu_n \in \mathbf{N}$. Then*

$$K_\lambda(0, \mu_0) + K_\lambda(\mu_0, \mu_1) + \cdots + K_\lambda(\mu_0 + \cdots + \mu_{n-1}, \mu_n) = K_\lambda(0, \mu_0 + \cdots + \mu_n).$$

Using a standard coupling argument, it is easy to establish the following facts.

Proposition 5.4. *Let $v \in \mathbb{X}$ and assume that $\lambda_1 \leq \lambda_2$. Then*

$$V_{\lambda_1}^v \leq_{st} V_{\lambda_2}^v, \quad (5.6)$$

and for $n \in \mathbb{N}$

$$V_{\leq n, \lambda_1}^v \leq_{st} V_{\leq n, \lambda_2}^v. \quad (5.7)$$

Proof. Construct $\xi_{\lambda_2}^v$ and then $\xi_{\lambda_1}^v$ by independent thinning. \square

The Proposition 5.4 implies monotonicity in the measure λ for $V_{\leq n}^v$ and V^v . We can state similar property for the first and second generations, but things are getting tricky for higher generations. This is an open question.

Proposition 5.5. *Let $v \in \mathbb{X}$, $m \in \{1, 2\}$ and assume that $\lambda_1 \leq \lambda_2$. Then*

$$V_{m, \lambda_1}^v \leq_{st} V_{m, \lambda_2}^v. \quad (5.8)$$

Proof. Construct $\xi_{\lambda_2}^v$ and then $\xi_{\lambda_1}^v$ by independent thinning. Then $V_{1, \lambda_1}^v \leq V_{1, \lambda_2}^v$ a.s.. The Proposition 5.1 shows that, given V_{1, λ_2}^v , the conditional distribution of V_{2, λ_2}^v is that of a Poisson process with an intensity measure $K_{\lambda_2}(\delta_v, V_{1, \lambda_2}^v)$. The statement follows from the facts that a Poisson process stochastically increases in the intensity measure and that K_λ is increasing in λ and the second coordinate, i.e. $K_{\lambda_2}(\delta_v, V_{1, \lambda_2}^v) \geq K_{\lambda_1}(\delta_v, V_{1, \lambda_1}^v)$. \square

Lemma 5.6. *Suppose that $\mu_1, \mu_2 \in \mathbf{N}_{<\infty}$ have disjoint support and set $\mu := \mu_1 + \mu_2$. Assume that ξ_{μ_1} and ξ_{μ_2} are independent RCMs with distributions ξ^{μ_1} and ξ^{μ_2} , respectively. Then*

$$V_n^\mu(\xi^\mu) \leq_{st} V_n^{\mu_1}(\xi^{\mu_1}) + V_n^{\mu_2}(\xi^{\mu_2}), \quad n \in \mathbb{N}_0, \quad (5.9)$$

$$V_{\leq n}^\mu(\xi^\mu) \leq_{st} V_{\leq n}^{\mu_1}(\xi^{\mu_1}) + V_{\leq n}^{\mu_2}(\xi^{\mu_2}), \quad n \in \mathbb{N}_0. \quad (5.10)$$

Proof. Define $V_{1,1}(\xi^\mu) := \{x \in \eta : x \sim \mu_1\}$ as the set of points from η which are connected to μ_1 in ξ^μ , and $V_{1,2}(\xi^\mu) := \{x \in \eta : x \sim \mu_2, x \not\sim \mu_1\}$. Then $V_{1,1}(\xi^\mu)$ and $V_{1,2}(\xi^\mu)$ are independent Poisson processes, and $V_1^\mu(\xi^\mu) = V_{1,1}(\xi^\mu) + V_{1,2}(\xi^\mu)$. For $k \in \mathbb{N}$ we define $V_{k,1}(\xi^\mu)$ as the set of points from $V_k^\mu(\xi^\mu)$ which are connected to $V_{k-1,1}(\xi^\mu)$ and $V_{k,2}(\xi^\mu)$ as the set of points from $V_k^\mu(\xi^\mu)$ which are connected to $V_{k-1,2}(\xi^\mu)$ but not to $V_{k-1,1}(\xi^\mu)$. Then $V_k^\mu(\xi^\mu) = V_{k,1}(\xi^\mu) + V_{k,2}(\xi^\mu)$. Moreover, $V_{k,1}(\xi^\mu)$ and $V_{k,2}(\xi^\mu)$ are conditionally independent Poisson processes given $C_{\leq k-1}^\mu(\xi^\mu)$. Let $f: \mathbf{N} \rightarrow \mathbb{R}_+$ be measurable and $n \in \mathbb{N}$. Then

$$\begin{aligned} \mathbb{E}f(V_n^\mu(\xi^\mu)) &= \mathbb{E} \mathbb{E}[f(V_n^\mu(\xi^\mu)) \mid C_{\leq n-1}^\mu(\xi^\mu)] \\ &= \mathbb{E} \iint f(\psi_n^1 + \psi_n^2) \Pi_{K(V_{\leq n-2}^\mu(\xi^\mu) + V_{n-1,1}(\xi^\mu), V_{n-1,2}(\xi^\mu))}(d\psi_n^2) \Pi_{K(V_{\leq n-2}^\mu(\xi^\mu), V_{n-1,1}(\xi^\mu))}(d\psi_n^1). \end{aligned}$$

Recursively, we get

$$\begin{aligned} \mathbb{E}f(V_n^\mu(\xi^\mu)) &= \int \cdots \int f(\psi_n^1 + \psi_n^2) \Pi_{K(\mu + \psi_1^1 + \psi_1^2 + \cdots + \psi_{n-2}^1 + \psi_{n-2}^2 + \psi_{n-1}^1, \psi_{n-1}^2)}(d\psi_n^2) \Pi_{K(\mu + \psi_1^1 + \psi_1^2 + \cdots + \psi_{n-2}^1 + \psi_{n-2}^2, \psi_{n-1}^1)}(d\psi_n^1) \\ &\quad \cdots \Pi_{K(\mu + \psi_1^1, \psi_1^2)}(d\psi_2^2) \Pi_{K(\mu, \psi_1^1)}(d\psi_1^2) \Pi_{K(\mu_1, \mu_2)}(d\psi_1^2) \Pi_{K(0, \mu_1)}(d\psi_1^1). \end{aligned} \quad (5.11)$$

On the other hand, we obtain from (5.5) and the independence of ξ_{μ_1} and ξ_{μ_2} that

$$\mathbb{E}f(V_n^{\mu_1}(\xi_{\mu_1}) + V_n^{\mu_2}(\xi_{\mu_2})) = \iint f(\psi_n^1 + \psi_n^2) H_n(0, \mu_1, d\psi_n^1) H_n(0, \mu_2, d\psi_n^2). \quad (5.12)$$

Assume now that f increases. We compare (5.11) and (5.12) taking into account two facts. First, Poisson processes increase stochastically in the intensity measure. Second, K decreases in the first argument and increases in the second. This implies

$$\mathbb{E}f(V_n^\mu(\xi^\mu)) \leq \mathbb{E}f(V_n^{\mu_1}(\xi_{\mu_1}) + V_n^{\mu_2}(\xi_{\mu_2})),$$

that is (5.9). The proof of (5.10) is the same, up to the fact that the argument of the function f has to be suitably modified. \square

Corollary 5.7. *Let $\mu \in \mathbf{N}_{<\infty}$ and $n \in \mathbb{N}_0$. Then*

$$\begin{aligned} V_n^\mu(\xi^\mu) &\leq_{st} \int V_n^x(\xi_x) \mu(dx), \\ V_{\leq n}^\mu(\xi^\mu) &\leq_{st} \int V_{\leq n}^x(\xi_x) \mu(dx). \end{aligned}$$

where ξ_x , $x \in \mu$, are independent and $\mathbb{P}(\xi_x \in \cdot) = \mathbb{P}(\xi^x \in \cdot)$.

Proof. Write $\mu = \delta_{x_1} + \cdots + \delta_{x_m}$ and apply Lemma 5.6 inductively with $\mu_1 = \delta_{x_1} + \cdots + \delta_{x_i}$ and $\mu_2 = \delta_{x_{i+1}}$ for $i = 1, \dots, m-1$. \square

In the following, we consider two families $\{\xi_x^{(n)}\}_{x \in V_n^v}$ and $\{\xi_x^{[n]}\}_{x \in V_n^v}$ of random graphs with the following properties:

1. Given $C_{\leq n}^v$, $\xi_x^{(n)}$ and $\xi_x^{[n]}$ are RCM's driven by $\eta_n + \delta_x$ and $\eta + \delta_x$, where η_n and η are Poisson processes with intensity measures $K_\lambda(V_{\leq n-1}^v)$ and λ respectively.
2. The members of the families are conditionally independent, given $C_{\leq n}^v$.

Proposition 5.8. *Let $v \in \mathbb{X}$ and $n, m \in \mathbb{N}_0$. Then*

$$V_{n+m}^v \leq_{st} \int V_m^x(\xi_x^{(n)}) V_n^v(dx).$$

Proof. Let $f: \mathbf{N} \rightarrow \mathbb{R}_+$ be measurable and increasing. By Proposition 5.1 the conditional distribution of V_{n+m}^v given $C_{\leq n}^v$ is that of $V_m^{V_n^v}(\xi^{(V_{\leq n-1}^v, V_n^v)})$, where $\xi^{(V_{\leq n-1}^v, V_n^v)}$ is a RCM based on $\eta_n + V_n^v$ and η_n is a Poisson process with intensity measure $K_\lambda(V_{\leq n-1}^v)$. Hence, by Corollary 5.7

$$\mathbb{E}f(V_{n+m}^v) = \mathbb{E} \mathbb{E}[f(V_{n+m}^v) \mid C_{\leq n}^v] = \mathbb{E} \mathbb{E}\left[f(V_m^{V_n^v}(\xi^{(V_{\leq n-1}^v, V_n^v)})) \mid C_{\leq n}^v\right] \leq \mathbb{E}f\left(\int V_m^x(\xi_x^{(n)}) V_n^v(dx)\right).$$

The assertion follows. \square

For $v \in \mathbb{X}$ and $n \in \mathbb{N}_0$ we define the *intensity measures* Λ_n^v of V_n^v by $\Lambda_n^v(B) := \mathbb{E}V_n^v(B)$ for $B \in \mathcal{X}$.

Proposition 5.9. *Let $v \in \mathbb{X}$ and $n \in \mathbb{N}_0$, $m \in \{1, 2\}$. Then*

$$V_{n+m}^v \leq_{st} \int V_m^x(\xi_x^{[n]}) V_n^v(dx).$$

Moreover, we get

$$\Lambda_{n+m}^v \leq \int \Lambda_m^x \Lambda_n^v(dx).$$

Proof. Let $f: \mathbf{N} \rightarrow \mathbb{R}_+$ be measurable and increasing. By Propositions 5.8 and 5.5,

$$\mathbb{E}f(V_{n+m}^v) = \mathbb{E} \mathbb{E}(f(V_{n+m}^v) \mid C_{\leq n}^v) \leq \mathbb{E}f\left(\int V_m^x(\xi_x^{(n)}) V_n^v(dx)\right) \leq \mathbb{E}f\left(\int V_m^x(\xi_x^{[n]}) V_n^v(dx)\right).$$

Since $\Lambda_0^v = \delta_v$ for the second statement, we can assume that $n \in \mathbb{N}$. For each $B \in \mathcal{X}$ we have

$$\Lambda_{n+m}^v(B) = \mathbb{E} \mathbb{E}(V_{n+m}^v(B) \mid C_{\leq n}^v) \leq \mathbb{E} \int \Lambda_m^x(B) V_n^v(dx) = \int \Lambda_m^x(B) \Lambda_n^v(dx),$$

where we have used Campbell's formula. \square

Proposition 5.10. *Let $v \in \mathbb{X}$ and $n, m \in \mathbb{N}$. Then*

$$V_{\leq n+m}^v \leq_{st} V_{\leq n-1}^v + \int V_{\leq m}^x(\xi_x^{(n)}) V_n^v(dx) \leq_{st} V_{\leq n-1}^v + \int V_{\leq m}^x(\xi_x^{[n]}) V_n^v(dx).$$

Proof. Let $f: \mathbf{N} \rightarrow \mathbb{R}_+$ be measurable and increasing. By Proposition 5.1 the conditional distribution of $V_{\leq n+m}^v$ given $C_{\leq n}^v$ is that of $V_{\leq n-1}^v + V_{\leq m}^{V_n^v}(\xi^{(V_{\leq n-1}^v, V_n^v)})$, where $\xi^{(V_{\leq n-1}^v, V_n^v)}$ is a RCM based on $\eta_n + V_n^v$ and η_n is a Poisson process with intensity measure $K_\lambda(V_{\leq n-1}^v)$. Hence, we obtain from Corollary 5.7 and Proposition 5.4

$$\begin{aligned} \mathbb{E}f(V_{\leq n+m}^v) &= \mathbb{E} \mathbb{E}[f(V_{\leq n+m}^v) \mid C_{\leq n}^v] \leq \mathbb{E}f\left(V_{\leq n-1}^v + \int V_{\leq m}^x(\xi_x^{(n)}) V_n^v(dx)\right) \\ &\leq \mathbb{E}f\left(V_{\leq n-1}^v + \int V_{\leq m}^x(\xi_x^{[n]}) V_n^v(dx)\right). \end{aligned}$$

\square

Corollary 5.11. *Let $v \in \mathbb{X}$ and $n \in \mathbb{N}$. Then*

$$V^v \leq_{st} V_{\leq n-1}^v + \int V^x(\xi_x^{[n]}) V_n^v(dx).$$

Proof. The claim follows from Proposition 5.10, since with probability one $V_{\leq n+m}^v \uparrow V^v$ and $V_{\leq m}^x(\xi_x^{[n]}) \uparrow V^x(\xi_x^{[n]})$ as $m \rightarrow \infty$. \square

Given $v \in \mathbb{X}$ and a measurable function $h: \mathbb{X} \rightarrow \mathbb{N}$, we define two spatial (Galton-Watson) branching processes $(W_k^{v,h})_{k \geq 0}$ and $(\widetilde{W}_k^{v,h})_{k \geq 0}$ along with a sequence of families of random graphs $\{\xi_x^k : x \in W_k^{v,h}\}$, $k \in \mathbb{N}_0$, recursively as follows. We set

$$W_0^{v,h} = \widetilde{W}_0^{v,h} = \delta_v, \quad W_1^{v,h} = V_{h(v)}^v, \quad \widetilde{W}_1^{v,h} = V_{\leq h(v)}^{v!},$$

and $\{\xi_x^0 : x \in W_0^{v,h}\} := \{\xi^v\}$. Given $k \geq 1$, $Z_k := ((W_n^{v,h}, \widetilde{W}_n^{v,h}))_{n \leq k}$ and $(\{\xi_x^n : x \in W_n^{v,h}\})_{n \leq k-1}$ we let $\{\xi_x^k : x \in W_k^{v,h}\}$ be a family of random graphs which are conditionally independent given Z_k and \mathbb{P} -a.s.

$$\mathbb{P}(\xi_x^k \in \cdot \mid Z_k) = \mathbb{P}(\xi^x \in \cdot), \quad x \in W_k^{v,h}.$$

Then we define

$$W_{k+1}^{v,h} := \int V_{h(x)}^x(\xi_x^k) W_k^{v,h}(dx), \quad \widetilde{W}_{k+1}^{v,h} := \int V_{\leq h(x)}^{x!}(\xi_x^k) W_k^{v,h}(dx).$$

Note that

$$\widetilde{W}_{k+1}^{v,h} = \int V_{\leq h(x)-1}^{x!}(\xi_x^k) W_k^{v,h}(dx) + W_{k+1}^{v,h}.$$

Hence, for every point $x \in W_k^{v,h}$ from the k -th generation we run an independent RCM driven by $\eta + \delta_x$, where η is a Poisson process with intensity measure λ and place all points of its $h(x)$ -th generation in our spatial branching process $k+1$ -th generation, i.e. $W_{k+1}^{v,h}$. The process $(\widetilde{W}_k^{v,h})_{k \geq 0}$ has a similar interpretation. We define

$$W_{\leq k}^{v,h} = \sum_{i=0}^k W_i^{v,h}, \quad W^{v,h} = \sum_{i=0}^{\infty} W_i^{v,h}, \quad \widetilde{W}_{\leq k}^{v,h} = \sum_{i=0}^k \widetilde{W}_i^{v,h}, \quad \widetilde{W}^{v,h} = \sum_{i=0}^{\infty} \widetilde{W}_i^{v,h}.$$

The special case $h \equiv n$ for some fixed $n \in \mathbb{N}$ is of particular importance. In that case we use the upper index n instead of h .

Remark 5.12. For each fixed $k \in \mathbb{N}$, the point process $\widetilde{W}_{\leq k}^{v,h}$ is locally finite. If the extinction probability of $W^{v,h}$ is equal to one, then this is also true for $\widetilde{W}^{v,h}$. Otherwise, one cannot be sure of the locally bounded property. Corollary 6.6 provides a simple sufficient condition (namely $D_\varphi^* < \infty$ and $c_n^*(t) < 1$ for some $n \in \mathbb{N}$) when $W^{v,n}$ is finite with probability one. In the stationary case, it suffices to assume that $c_n^*(t) \leq 1$, since the total size of $W^{v,n}$ coincides with the total size of a Galton-Watson process with offspring distribution $|V_n^0|$.

We have the following useful property.

Proposition 5.13. *Let $v \in \mathbb{X}$ and $k, n \in \mathbb{N}$. Then*

$$W_k^{v,n} \leq_{st} W_{kn}^{v,1}, \tag{5.13}$$

$$W_{\leq k}^{v,n} \leq_{st} \sum_{i=1}^k W_{in}^{v,1}. \tag{5.14}$$

In particular, if $k = 1$, then

$$V_n^v \leq_{st} W_n^{v,1}. \tag{5.15}$$

Proof. Define a kernel \tilde{K} from \mathbf{N} to \mathbf{N} by

$$\tilde{K}(\mu, \cdot) := \int K_\lambda(0, \delta_x, \cdot) \mu(dx). \quad (5.16)$$

By Bernoulli's inequality, we have

$$K_\lambda(\mu, \mu', \cdot) \leq \tilde{K}(\mu', \cdot), \quad \mu, \mu' \in \mathbf{N}. \quad (5.17)$$

Taking an increasing and measurable $f: \mathbf{N} \rightarrow \mathbb{R}$, we therefore obtain from (5.5) and the monotonicity properties of a Poisson process that

$$\mathbb{E}f(V_n^v) \leq \int \cdots \int f(\psi_n) \Pi_{\tilde{K}(\psi_{n-1})}(d\psi_n) \cdots \Pi_{\tilde{K}(\psi_1)}(d\psi_2) \Pi_{\tilde{K}(\delta_v)}(d\psi_1) = \mathbb{E}f(W_n^{v,1}). \quad (5.18)$$

This is (5.13) for $k = 1$, i.e. (5.15).

By the definition of $W_2^{v,n}$ and (5.5) we have

$$\mathbb{E}f(W_2^{v,n}) = \mathbb{E} \int f(\psi) H'_n(V_n^v, d\psi), \quad (5.19)$$

where for given $m \in \mathbb{N}$ and $\delta_{\mathbf{x}_m} \in \mathbf{N}_{<\infty}$

$$H'_n(\mu, \cdot) := \int \cdots \int \mathbf{1}\{\psi^1 + \cdots + \psi^m \in \cdot\} H_n(0, \delta_{x_1}, d\psi^1) \cdots H_n(0, \delta_{x_m}, d\psi^m).$$

Using (5.17) and the monotonicity properties of a Poisson process in the definition (5.4) of kernels H_n once again, we see that

$$\begin{aligned} \int f(\psi) H'_n(\mu, d\psi) &\leq \int \cdots \int f(\psi_n^1 + \cdots + \psi_n^m) \Pi_{\tilde{K}(\psi_{n-1}^1)}(d\psi_n^1) \cdots \Pi_{\tilde{K}(\psi_{n-1}^m)}(d\psi_n^m) \times \cdots \\ &\quad \times \Pi_{\tilde{K}(\delta_{x_1})}(d\psi_1^1) \cdots \Pi_{\tilde{K}(\delta_{x_m})}(d\psi_1^m). \end{aligned}$$

By the definition (5.16) of the kernel \tilde{K} and the fundamental properties of a Poisson process, the above m innermost integrals equal

$$\int f(\psi_n) \Pi_{\tilde{K}(\psi_{n-1}^1 + \cdots + \psi_{n-1}^m)}(d\psi_n).$$

Proceeding inductively, we obtain that

$$\int f(\psi) H'_n(\mu, d\psi) \leq \int \cdots \int f(\psi_n) \Pi_{\tilde{K}(\psi_{n-1})}(d\psi_n) \cdots \Pi_{\tilde{K}(\mu)}(d\psi_1).$$

The above right-hand side is an increasing function of μ . Hence, we can apply (5.13) for $k = 1$ to obtain from (5.19)

$$\mathbb{E}f(W_2^{v,n}) \leq \int \cdots \int f(\psi_n) \Pi_{\tilde{K}(\psi_{n-1})}(d\psi_n) \cdots \Pi_{\tilde{K}(\chi_n)}(d\psi_1) \Pi_{\tilde{K}(\chi_{n-1})}(d\chi_n) \cdots \Pi_{\tilde{K}(\delta_v)}(d\chi_1) = \mathbb{E}f(W_{2n}^{v,1}).$$

Hence, we have (5.13) for $k = 2$. The case of a general k can be treated analogously. The second assertion (5.14) can be proved in the same way, modifying the arguments of the function f in an appropriate way. \square

In the following result, and also later, we consider a Galton-Watson process $(W_k)_{k \geq 0}$ with Poisson offspring distribution with parameter $D_\varphi^* = \|D_\varphi\|_\infty$ starting with $W_0 = 1$. Then W_k is the number of points in the k -th generation. We set $W_{\leq k} := \sum_{i=0}^k W_i$.

Proposition 5.14. *Let $v \in \mathbb{X}$ and $n \in \mathbb{N}$. Then*

$$|W_n^{v,1}| \leq_{st} W_n, \quad |W_{\leq n}^{v,1}| \leq_{st} W_{\leq n}.$$

Proof. Note that the total size of the offspring distribution $|V_1^x(\xi_x)|$ is a Poisson random variable with parameter $D_\varphi(x)$. Recall the definition (5.16). Taking an increasing and measurable $f: \mathbb{N} \rightarrow \mathbb{R}$, we obtain from the monotonicity properties of a Poisson process that

$$\begin{aligned} \mathbb{E}f(|W_n^{v,1}|) &= \int \cdots \int f(|\psi_n|) \Pi_{\tilde{K}(\psi_{n-1})}(d\psi_n) \cdots \Pi_{\tilde{K}(\psi_1)}(d\psi_2) \Pi_{\tilde{K}(\delta_v)}(d\psi_1) \\ &\leq \int \cdots \int f(|\psi_n|) \Pi_{D_\varphi^* \psi_{n-1}}(d\psi_n) \cdots \Pi_{D_\varphi^* \psi_1}(d\psi_2) \Pi_{D_\varphi^* \delta_v}(d\psi_1) \leq \mathbb{E}f(W_n). \end{aligned}$$

The proof of the second inequality is the same, up to the fact that the argument of the function f has to be suitably modified. \square

The following results are crucial for later purposes.

Proposition 5.15. *Let $v \in \mathbb{X}$ and $n, k \in \mathbb{N}$. Then*

$$V_{\leq kn}^v \leq_{st} \widetilde{W}_{\leq k}^{v,n}.$$

Proof. By Proposition 5.10, from the similar definitions of $\{\xi_x^{[n]} : x \in V_n^v\}$ and $\{\xi_x^1 : x \in V_n^v\}$ we get

$$V_{\leq kn}^v \leq_{st} V_{\leq n-1}^v + \int V_{\leq (k-1)n}^{x_1}(\xi_{x_1}^1) V_n^v(dx_1). \quad (5.20)$$

Define a point process $V_n^{[2]}$ on $\mathbb{X} \times \mathbb{X}$ by

$$V_n^{[2]} := \iint \mathbf{1}\{(x_1, x_2) \in \cdot\} V_n^{x_1}(\xi_{x_1}^1, dx_2) V_n^v(dx_1).$$

Let $\{\xi_{x_1, x_2}^{[2]} : (x_1, x_2) \in V_n^{[2]}\}$ be a family of random graphs which are conditionally independent given $V_n^{[2]}$ and \mathbb{P} -a.s.

$$\mathbb{P}(\xi_{x_1, x_2}^{[2]} \in \cdot \mid V_n^{[2]}) = \mathbb{P}(\xi^{x_2} \in \cdot), \quad (x_1, x_2) \in V_n^{[2]}.$$

This implies that for each $x_1 \in V_n^v$ the random graphs $\xi_{x_1, x_2}^{[2]}$, $x_2 \in V_n^{x_1}(\xi_{x_1}^1)$, are conditionally independent given $V_n^{x_1}(\xi_{x_1}^1)$ and

$$\mathbb{P}(\xi_{x_1, x_2}^{[2]} \in \cdot \mid V_n^{x_1}(\xi_{x_1}^1)) = \mathbb{P}(\xi^{x_2} \in \cdot), \quad x_2 \in V_n^{x_1}(\xi_{x_1}^1).$$

Therefore, we can apply Proposition 5.10 in (5.20) to the conditional distribution (w.r.t. $V_n^{[2]}$) to see that

$$V_{\leq kn}^v \leq_{st} V_{\leq n-1}^v + \int V_{\leq n-1}^{x_1}(\xi_{x_1}^1) V_n^v(dx_1) + \iint V_{\leq (k-2)n}^{x_2}(\xi_{x_1, x_2}^{[2]}) V_n^{x_1}(\xi_{x_1}^1, dx_2) V_n^v(dx_1),$$

It is easy to see that the distribution of the above right-hand side does not change when replacing $\xi_{x_1, x_2}^{[2]}$ by $\xi_{x_2}^2$. It follows that

$$V_{\leq kn}^v \leq_{st} V_{\leq n-1}^v + \int V_{\leq n-1}^{x_1}(\xi_{x_1}^1) V_n^v(dx_1) + \iint V_{\leq (k-2)n}^{x_2}(\xi_{x_2}^2) V_n^{x_1}(\xi_{x_1}^1, dx_2) V_n^v(dx_1).$$

Proceeding inductively, we obtain

$$\begin{aligned} V_{\leq kn}^v &\leq_{st} V_{\leq n-1}^v + \int V_{\leq n-1}^{x_1}(\xi_{x_1}^1) V_n^v(dx_1) + \cdots + \int \cdots \int V_{\leq n-1}^{x_{k-2}}(\xi_{x_{k-2}}^{k-2}) V_n^{x_{k-3}}(\xi_{x_{k-3}}^{k-3}, dx_{k-2}) \cdots V_n^v(dx_1) \\ &\quad + \int \cdots \int V_{\leq n}^{x_{k-1}}(\xi_{x_{k-1}}^{k-1}) V_n^{x_{k-2}}(\xi_{x_{k-2}}^{k-2}, dx_{k-1}) \cdots V_n^v(dx_1). \end{aligned} \quad (5.21)$$

Here, the last term can be written as

$$\begin{aligned} &\int \cdots \int V_n^{x_{k-2}}(\xi_{x_{k-2}}^{k-2}) V_n^{x_{k-3}}(\xi_{x_{k-3}}^{k-3}, dx_{k-2}) \cdots V_n^v(dx_1) \\ &\quad + \int \cdots \int V_{\leq n}^{x_{k-1}}(\xi_{x_{k-1}}^{k-1}) V_n^{x_{k-2}}(\xi_{x_{k-2}}^{k-2}, dx_{k-1}) \cdots V_n^v(dx_1) \\ &= \int \cdots \int V_n^{x_{k-2}}(\xi_{x_{k-2}}^{k-2}) V_n^{x_{k-3}}(\xi_{x_{k-3}}^{k-3}, dx_{k-2}) \cdots V_n^v(dx_1) + \widetilde{W}_k^{v,n}. \end{aligned}$$

Inserting this into (5.21), performing the preceding step several times, we end up with

$$V_{\leq kn}^v \leq_{st} V_{\leq n}^v + \widetilde{W}_1^{v,n} + \cdots + \widetilde{W}_k^{v,n} = \widetilde{W}_{\leq k}^{v,n}.$$

This concludes the proof. \square

Corollary 5.16. *Let $v \in \mathbb{X}$ and $k \in \mathbb{N}$. Then*

$$V_{\leq k}^v \leq_{st} W_{\leq k}^{v,1}.$$

Proof. The statement follows from Proposition 5.15 for $n = 1$ and the observation that $\widetilde{W}_{\leq k}^{v,1} \equiv W_{\leq k}^{v,1}$. \square

Proposition 5.17. *Let $v \in \mathbb{X}$ and $h: \mathbb{X} \rightarrow \mathbb{N}$ be a measurable function. Then*

$$V^v \leq_{st} \widetilde{W}^{v,h}.$$

Proof. As in the proof of Proposition 5.15 it follows for each $n \in \mathbb{N}$ that

$$V_{\leq n}^v \leq_{st} V_{\leq h(v)-1}^v + \int V_{\leq h(x_1)-1}^{x_1}(\xi_{x_1}^1) V_{h(v)}^v(dx_1) + \iint V_{\leq n-h(v)-h(x_1)}^{x_2}(\xi_{x_1,x_2}^{[2]}) V_{h(x_1)}^{x_1}(\xi_{x_1}^1, dx_2) V_{h(v)}^v(dx_1).$$

Note that the distribution of the above right-hand side does not change upon replacing $\xi_{x_1,x_2}^{[2]}$ by $\xi_{x_2}^2$. It follows that

$$V_{\leq n}^v \leq_{st} V_{\leq h(v)-1}^v + \int V_{\leq h(x_1)-1}^{x_1}(\xi_{x_1}^1) V_{h(v)}^v(dx_1) + \iint V_{\leq n-h(v)-h(x_1)}^{x_2}(\xi_{x_2}^2) V_{h(x_1)}^{x_1}(\xi_{x_1}^1, dx_2) V_{h(v)}^v(dx_1).$$

Proceeding inductively, since $h(x) \geq 1$ for any $x \in \mathbb{X}$, we obtain for any $n \in \mathbb{N}$

$$V_{\leq n}^v \leq_{st} \widetilde{W}_{\leq n}^{v,h} \leq \widetilde{W}^{v,h}.$$

This concludes the proof, since with probability one $V_{\leq n}^v \uparrow V^v$ as $n \rightarrow \infty$. \square

Corollary 5.18. *Let $v \in \mathbb{X}$ and $n \in \mathbb{N}$. Then*

$$V^v \leq_{st} \widetilde{W}^{v,n}.$$

6 A criterion for subcriticality and exponential moments

We establish the setting of Section 5 with intensity measure λ replaced by $t\lambda$ for some $t \geq 0$. We use the so-called generations method to build lower bounds on t_T , see e.g. [29, 38, 30, 31, 32]. As is common in percolation theory, we denote the underlying probability measure by \mathbb{P}_t , to stress the dependence on the intensity parameter.

Lemma 6.1. *We have $t_T \geq (D_\varphi^*)^{-1}$. Moreover, we have $t_T > 0$ if and only if $D_\varphi^* < \infty$,*

Proof. If $D_\varphi^* = 0$, then each Poisson point is isolated and $t_T = \infty$. If $D_\varphi^* = \infty$, then $c_1^*(t) = tD_\varphi^* = \infty$ for any $t > 0$ and $t_T = 0$. Let $t \geq 0$ and assume that $0 < D_\varphi^* < \infty$. The Proposition 5.13 implies that $c_n^v(t) \leq \mathbb{E}_t |W_n^{v,1}|$. By Proposition 5.14 we have $\mathbb{E}_t |W_n^{v,1}| \leq \mathbb{E}_t W_n = (c_1^*(t))^n$ for any $n \in \mathbb{N}$. Therefore, $t_T \geq 1/D_\varphi^* > 0$. \square

In the remainder of the section, we shall assume that $D_\varphi^* < \infty$.

Remark 6.2. One can attempt to improve the lower bound of t_T by obtaining an estimate of the form

$$\mathbb{E}_t(|V_{n+l}^v| \mid C_{\leq n}^v) \leq \gamma(t)|V_n^v|$$

for all $n \geq n_0$ and some $l, n_0 \in \mathbb{N}$. Then as soon as $\gamma(t_0) < 1$ there is no percolation and $t_T > t_0$. It is true that in continuous models, obtaining such estimates for $l \geq 2$ involves appreciable technical difficulties.

By Proposition 5.9 for $n \in \mathbb{N}_0$ we have

$$c_{n+2}^v(t) \leq c_2^*(t)c_n^v(t). \quad (6.1)$$

This easily implies that if $c_2^*(t) < 1$, then $t < t_T$. One of the main goals of this section is to show that if $D_\varphi^* < \infty$ and $c_n^*(t) < 1$ for some $n \in \mathbb{N}$, then $t < t_T$.

Lemma 6.3. *Let $n, k \in \mathbb{N}$ and assume that $D_\varphi^* < \infty$. Then for any $t, \delta > 0$*

$$\operatorname{ess\,sup}_{v \in \mathbb{X}} \mathbb{E}_t e^{\delta |W_{\leq k}^{v,n}|} < \infty.$$

Proof. By Proposition 5.13 we have $W_{\leq k}^{v,n} \leq_{st} W_{\leq kn}^{v,1}$. Then by Proposition 5.14 we obtain

$$\operatorname{ess\,sup}_{v \in \mathbb{X}} \mathbb{E}_t e^{\delta |W_{\leq k}^{v,n}|} \leq \mathbb{E}_t e^{\delta W_{\leq kn}^{v,1}}.$$

Since the offspring distribution of $W_{\leq kn}$ is Poisson with parameter $c_1^*(t) < \infty$, it is well-known that $W_{\leq kn}$ has exponential moments of each order; see e.g. [33]. \square

Corollary 6.4. *Assume that $D_\varphi^* < \infty$ and let $n \in \mathbb{N}$. Then for any $t, \delta > 0$*

$$\operatorname{ess\,sup}_{v \in \mathbb{X}} \mathbb{E}_t e^{\delta |V_{\leq n}^v|} < \infty.$$

Proof. By Proposition 5.15 we have $V_{\leq n}^v \leq_{st} W_{\leq n}^{v,1}$. Then the result follows from Lemma 6.3. \square

Theorem 6.5. *Let $h: \mathbb{X} \rightarrow \mathbb{N}$ be a measurable bounded function and $t \geq 0$. Assume that $D_\varphi^* < \infty$ and $c_h^*(t) := \operatorname{ess\,sup}_{v \in \mathbb{X}} c_{h(v)}^v(t) < 1$. Then*

$$\operatorname{ess\,sup}_{v \in \mathbb{X}} \mathbb{E}_t |\widetilde{W}^{v,h}| \leq \frac{c_{\leq h^*}^*(t)}{1 - c_h^*(t)} < \infty,$$

where $h^* := \|h\|_\infty$.

Proof. By Fubini's theorem, we have

$$\begin{aligned}\mathbb{E}_t|W^{v,h}| &= 1 + c_{h(v)}^v(t) + \sum_{k \geq 1} \mathbb{E}_t \int |V_{h(x)}^x(\xi_x^k)| W_k^{v,h}(dx) = 1 + c_{h(v)}^v(t) + \sum_{k \geq 1} \mathbb{E}_t \int c_{h(x)}^x(t) W_k^{v,h}(dx) \\ &\leq 1 + c_{h(v)}^v(t) + c_h^*(t)(\mathbb{E}_t|W^{v,h}| - 1).\end{aligned}$$

Therefore, $\mathbb{E}_t|W^{v,h}| \leq (1 + c_{h(v)}^v(t) - c_h^*(t))/(1 - c_h^*(t)) \leq (1 - c_h^*(t))^{-1}$ for any $v \in \mathbb{X}$. Moreover, by Corollary 6.4 and Fubini's theorem, we obtain that for any $v \in \mathbb{X}$

$$\begin{aligned}\mathbb{E}_t|\widetilde{W}^{v,h}| &= c_{\leq h(v)}^v(t) + \sum_{k \geq 1} \mathbb{E}_t \int |V_{\leq h(x)}^{x!}(\xi_x^k)| W_k^{v,h}(dx) = c_{\leq h(v)}^v(t) + \sum_{k \geq 1} \mathbb{E}_t \int (c_{\leq h(x)}^x(t) - 1) W_k^{v,h}(dx) \\ &\leq c_{\leq h(v)}^v(t) + (c_{\leq h}^*(t) - 1)(\mathbb{E}_t|W^{v,h}| - 1) < \frac{c_{\leq h}^*(t)}{1 - c_h^*(t)} < \infty.\end{aligned}$$

This proves the result. \square

Corollary 6.6. *Let $n \in \mathbb{N}$ and $t \geq 0$. If $D_\varphi^* < \infty$ and $c_n^*(t) < 1$, then $c^*(t) \leq c_{\leq n}^*(t)/(1 - c_n^*(t)) < \infty$ and $t < t_T$.*

Proof. The assertion follows from Corollary 5.18 and Theorem 6.5 with $h \equiv n$. \square

In the following, we generalize Corollary 6.6 for the case where it is known at which point of the underlying space the mean cluster size takes its maximal value.

Proposition 6.7 (A special criterion for subcriticality). *Let $v_0 \in \mathbb{X}$, $n \in \mathbb{N}$ and $t \geq 0$. If $D_\varphi^* < \infty$, $c^{v_0}(t) = c^*(t)$ and $c_n^{v_0}(t) < 1$, then $c^*(t) \leq c_{\leq n-1}^{v_0}(t)/(1 - c_n^{v_0}(t)) < \infty$ and $t < t_T$.*

Proof. By Corollary 5.11 and Fubini's theorem, we have

$$c^*(t) = c^{v_0}(t) \leq c_{\leq n-1}^{v_0}(t) + \mathbb{E}_t \int c^x(t) V_n^{v_0}(dx) \leq c_{\leq n-1}^{v_0}(t) + c_n^{v_0}(t) c^{v_0}(t).$$

Therefore, $c^{v_0}(t) \leq c_{\leq n-1}^{v_0}(t)/(1 - c_n^{v_0}(t)) < \infty$. \square

Theorem 6.8. *Under the conditions of Theorem 6.5 there exists $\delta = \delta(t, h^*) > 0$ such that*

$$\operatorname{ess\,sup}_{v \in \mathbb{X}} \mathbb{E}_t e^{\delta|\widetilde{W}^{v,h}|} < \infty.$$

Proof. To describe the total population sizes of $W^{v,h}$ and $\widetilde{W}^{v,h}$, we define an exploration process. Let's consider the following spatial Markov process $(X_k)_{k \geq 0} = (Y_k, Z_k)_{k \geq 0}$ along with a sequence of families of random graphs $\{\xi_x^k : x \in Z_k\}$, $k \in \mathbb{N}_0$, recursively as follows. We set

$$X_0 = (\delta_v, \delta_v), \quad X_1 = (V_{\leq h(v)}^v, V_{h(v)}^v),$$

and $\{\xi_x^0 : x \in Z_0\} := \{\xi^v\}$. Given $k \geq 1$, $(X_n)_{n \leq k}$ and $(\{\xi_x^n : x \in Z_n\})_{n \leq k-1}$ we let $\{\xi_x^k : x \in Z_k\}$ be a family of random graphs which are conditionally independent given Z_k and \mathbb{P} -a.s.

$$\mathbb{P}(\xi_x^k \in \cdot \mid Z_k) = \mathbb{P}(\xi^x \in \cdot), \quad x \in Z_k.$$

Then we define

$$\begin{aligned}Y_{k+1} &= Y_k + \int \mathbf{1}\{d(v, x) = \min_{y \in Z_k} d(v, y)\} V_{\leq h(x)}^{x!}(\xi_x^k) Z_k(dx), \\ Z_{k+1} &= Z_k + \int \mathbf{1}\{d(v, x) = \min_{y \in Z_k} d(v, y)\} (V_{h(x)}^x(\xi_x^k) - \delta_x) Z_k(dx).\end{aligned}$$

Let $\tau := \min(k \geq 1 : Z_k = \emptyset)$. Note that τ is a stopping time w.r.t. $\{Z_k\}_{k \in \mathbb{N}}$. Moreover, $\tau = |W^{v,h}|$ and $Y_\tau = \widetilde{W}^{v,h}$ in distribution. Then we can use the well-known test function criteria to prove the existence of an exponential moment for τ (see [21, Corollary 2, p. 115]). Let $\delta, \varepsilon > 0$ and $\tau_k := \min(\tau, k)$ for $k \geq 1$. Then for any $k \geq 1$ with probability one

$$e^{\delta \tau_k} \leq e^{\delta \tau_k + \varepsilon |Z_{\tau_k}|} = e^{\varepsilon |Z_0|} + \sum_{m=0}^{\tau_k-1} \left(e^{\delta(m+1) + \varepsilon |Z_{m+1}|} - e^{\delta m + \varepsilon |Z_m|} \right).$$

Note that by Corollary 6.4 we have as $\varepsilon \rightarrow 0$

$$\begin{aligned} \mathbb{E}_t \left(e^{\delta(m+1) + \varepsilon |Z_{m+1}|} - e^{\delta m + \varepsilon |Z_m|} \mid Z_m \right) \\ = e^{\delta m + \varepsilon |Z_m|} \mathbb{E}_t \left(\exp \left(\delta + \varepsilon \int \mathbf{1}\{d(v, x) = \min_{y \in Z_m} d(v, y)\} (|V_{h(x)}^x(\xi_x^m)| - 1) Z_m(dx) \right) - 1 \mid Z_m \right) \\ \sim e^{\delta m + \varepsilon |Z_m|} \left(e^\delta \left(1 + \varepsilon \int \mathbf{1}\{d(v, x) = \min_{y \in Z_m} d(v, y)\} (c_{h(x)}^x(t) - 1) Z_m(dx) \right) - 1 \right) \\ \leq e^{\delta m + \varepsilon |Z_m|} \left(e^\delta (1 + \varepsilon (c_h^*(t) - 1)) - 1 \right). \end{aligned}$$

Then there exist $\varepsilon, \delta > 0$ such that for any $m \geq 0$

$$\mathbb{E}_t \left(e^{\delta(m+1) + \varepsilon |Z_{m+1}|} - e^{\delta m + \varepsilon |Z_m|} \right) = \mathbb{E}_t \mathbb{E}_t \left(e^{\delta(m+1) + \varepsilon |Z_{m+1}|} - e^{\delta m + \varepsilon |Z_m|} \mid Z_m \right) \leq 0.$$

Therefore, $\mathbb{E}_t e^{\delta \tau_k} \leq \mathbb{E}_t e^{\varepsilon |Z_0|} = e^\varepsilon$ for any $k \geq 1$. Letting $k \rightarrow \infty$ we obtain the light tail property for τ uniformly in $v \in \mathbb{X}$.

Note that by Propositions 5.15 and 5.14 we have for any $k \geq 1$

$$\begin{aligned} \mathbb{E}_t e^{\delta |Y_k|} &= \mathbb{E}_t \left(e^{\delta |Y_{k-1}|} \mathbb{E}_t \left(\exp \left(\delta \int \mathbf{1}\{d(v, x) = \min_{y \in Z_{k-1}} d(v, y)\} |V_{\leq h(x)}^{x!}(\xi_x^{k-1})| Z_{k-1}(dx) \right) \mid X_{k-1} \right) \right) \\ &= \mathbb{E}_t \left(e^{\delta |Y_{k-1}|} \int \mathbf{1}\{d(v, x) = \min_{y \in Z_{k-1}} d(v, y)\} \mathbb{E}_t(e^{\delta |V_{\leq h(x)}^{x!}(\xi_x^{k-1})|} \mid Z_{k-1}) Z_{k-1}(dx) \right) \\ &\leq \mathbb{E}_t e^{\delta |Y_{k-1}|} \mathbb{E}_t e^{\delta (W_{\leq h^*} - 1)} \leq \left(\mathbb{E}_t e^{\delta (W_{\leq h^*} - 1)} \right)^k. \end{aligned}$$

By Theorem 6.5 $|\widetilde{W}^{v,h}|$ is a proper random variable. Then, by Fubini's theorem, Cauchy–Schwarz inequality, and the previous inequality, we also have

$$\begin{aligned} \mathbb{E}_t e^{\delta |\widetilde{W}^{v,h}|} &= \mathbb{E}_t \left(e^{\delta |\widetilde{W}^{v,h}|} \sum_{k=1}^{\infty} \mathbf{1}\{\tau = k\} \right) = \sum_{k=1}^{\infty} \mathbb{E}_t (e^{\delta |Y_k|} \mathbf{1}\{\tau = k\}) \\ &\leq \sum_{k=1}^{\infty} \sqrt{\mathbb{E}_t e^{2\delta |Y_k|} \mathbb{P}_t(\tau = k)} \leq \sum_{k=1}^{\infty} \sqrt{(\mathbb{E}_t e^{2\delta (W_{\leq h^*} - 1)})^k \mathbb{P}_t(\tau = k)}. \end{aligned}$$

Since $W_{\leq h^*}$ has exponential moments of all orders (see e.g. [33]) and $\lim_{\delta \rightarrow 0} \mathbb{E}_t e^{2\delta (W_{\leq h^*} - 1)} = 1$ we get the required result from the uniform light tail property for τ . \square

Corollary 6.9. *Under the conditions of Corollary 6.6 there exists $\delta \equiv \delta(t, n) > 0$ such that*

$$\operatorname{ess\,sup}_{v \in \mathbb{X}} \mathbb{E}_t e^{\delta |V^v|} < \infty. \quad (6.2)$$

Proof. The claim follows from Corollary 5.18 and Theorem 6.8 with $h \equiv n$. \square

Theorem 6.10. *Suppose that $t < t_T$. Then there exists $\delta \equiv \delta(t) > 0$ such that (6.2) holds.*

Proof. Since $t < t_T$ we have $c_1^*(t) = tD_\varphi^* \leq c^*(t) < \infty$. Define $N := \lceil 2c^*(t) \rceil$ and

$$A_i := \{v \in \mathbb{X} : c_i^v(t) \leq 1/2\} \setminus \left(\bigcup_{j=1}^{i-1} A_j \right), \quad i \in \mathbb{N}.$$

Then $\lambda(\bigcap_{i=1}^N A_i^c) = 0$, since otherwise $c^*(t) > N/2 \geq c^*(t)$. Let n be the smallest number such that $\lambda(\bigcap_{i=1}^n A_i^c) = 0$. By Proposition 5.17 we have that $V^v \leq_{st} \widetilde{W}^{v,h}$, where $h(v) := i$ for $v \in A_i$ and $h(v) := 1$, otherwise. Therefore, the required result follows from Theorem 6.8. \square

Example 6.11. Take \mathbb{X} as the d -dimensional hyperbolic space \mathbb{H}^d for some $d \geq 2$ equipped with the hyperbolic metric $d_{\mathbb{H}^d}$; see e.g. [20] and the references given there. Assume that λ is given by the Haar measure \mathcal{H}^d on \mathbb{R}^d . Assume that the connection function is given by $\varphi(x, y) = \tilde{\varphi}(d_{\mathbb{H}^d}(x, y))$ for some measurable $\tilde{\varphi}: \mathbb{R}_+ \rightarrow [0, 1]$. Fix a point $o \in \mathbb{H}^d$. Since the space \mathbb{H}^d is homogeneous, we can argue as in Remark 4.1 to see that

$$t_c = \sup\{t \geq 0 : \mathbb{P}_t(|C^o| < \infty) = 0\}, \quad t_T = \sup\{t \geq 0 : \mathbb{E}_t|C^o| < \infty\}.$$

It was proved in [9] that $t_c < \infty$ if and only if $\int \varphi(o, x) \mathcal{H}^d(dx) > 0$. In accordance with our Lemma 6.1 it was also shown there that $t_T > 0$ if and only if $\int \varphi(o, x) \mathcal{H}^d(dx) < \infty$. Assume now that $\int \varphi(o, x) \mathcal{H}^d(dx) \in (0, \infty)$. It was proved in [9] that $t_c = t_T$. Hence our Theorem 6.10 yields a strong sharp phase transition at t_c , just as in the stationary (unmarked) Euclidean case.

7 Diameter distribution

We establish the setting of Section 5 with an intensity measure $t\lambda$ for $t \geq 0$. Denote by

$$d_m(A_1, A_2) := \sup_{x \in A_1, y \in A_2} d(x, y)$$

the maximum distance between the points of $A_1, A_2 \subset \mathbb{X}$. We use the convention that $d_m(A, \emptyset) := 0$ for any $A \subset \mathbb{X}$. Define by $D(A) := d_m(A, A)$ the diameter of a set $A \subset \mathbb{X}$. We will also use the same notations for $\mu \in \mathbf{G}$ identifying A with $V(\mu)$.

Lemma 7.1. *Let $A_1, A_2 \subset \mathbb{X}$, $A = A_1 \cup A_2$, and $v \in A$. If $A_1 \cap A_2 \neq \emptyset$, then*

$$D(A) \leq \min(D(A_1) + D(A_2), 2d_m(v, A)).$$

Proof. Note that for any $x \in A_1 \cap A_2$ by the triangle inequality, we have

$$d_m(A_1, A_2) \leq d_m(x, A_1) + d_m(x, A_2) \leq d_m(A_1 \cap A_2, A_1) + d_m(A_1 \cap A_2, A_2) \leq D(A_1) + D(A_2).$$

Therefore, the result follows from the fact that $D(A) = \max(D(A_1), D(A_2), d_m(A_1, A_2))$, and a simple consequence of the triangle inequality, i.e. $D(A) \leq 2d_m(v, A)$. \square

Denote for $v \in \mathbb{X}$ and $n \in \mathbb{N}$ the maximum length of the edges between generations $n-1$ and n by

$$E_n^v := \max_{x \in V_{n-1}^v, y \in V_n^v : x \sim y} d(x, y).$$

We also define by $E_{\leq n}^v := \max(E_1^v, E_2^v, \dots, E_n^v)$ and $E^v := \sup_{n \in \mathbb{N}} E_{\leq n}^v$ the maximal length among the edges between generations in $C_{\leq n}^v$ and C^v respectively. Note that $E_1^v = d_m(v, V_1^v)$. For $v \in \mathbb{X}$ and $t, r \geq 0$ we denote by

$$\phi_t^v(r) := 1 - \exp\left(-t \int_{B_r^c(v)} \varphi(v, x) \lambda(dx)\right),$$

where $B_r(v) := \{x \in \mathbb{X} : d(v, x) \leq r\}$ is the closed ball of radius r centered at a point v in \mathbb{X} . We also denote by $\phi_t^*(r) := \text{ess sup}_{v \in \mathbb{X}} \phi_t^v(r)$.

Lemma 7.2. *Let $v \in \mathbb{X}$ and $t, r \geq 0$. Then $\mathbb{P}_t(E_1^v > r) = \phi_t^v(r) \leq \phi_t^*(r)$.*

Proof. The claim follows from Proposition 5.1 since V_1^v is a Poisson process with intensity measure $K_{t\lambda}(0, \delta_v)$. \square

Proposition 7.3. *Let $v \in \mathbb{X}$, $n \in \mathbb{N}$ and $r \geq 0$. Then*

$$\mathbb{P}_t(E_{\leq n}^v > r) \leq c_{\leq n-1}^v(t) \phi_t^*(r), \quad \mathbb{P}_t(E^v > r) \leq c^v(t) \phi_t^*(r).$$

Proof. By subadditivity of a probability measure and Proposition 5.1, we have

$$\begin{aligned} \mathbb{P}_t(E_{\leq n}^v > r) &= \mathbb{P}_t\left(\bigcup_{k=1}^n \{E_k^v > r\}\right) \leq \sum_{k=1}^n \mathbb{P}_t(E_k^v > r) = \sum_{k=1}^n \mathbb{P}_t\left(\bigcup_{x \in V_{k-1}^v} \left\{ \max_{y \in V_k^v : x \sim y} d(x, y) > r \right\}\right) \\ &\leq \sum_{k=1}^n \mathbb{E}_t \int \mathbb{P}_t\left(\max_{y \in V_k^v : x \sim y} d(x, y) > r \mid C_{\leq k-1}^v\right) V_{k-1}^v(dx) \\ &= \sum_{k=1}^n \mathbb{E}_t \int 1 - \exp\left(-t \int_{B_r^c(x)} \varphi(x, y) \bar{\varphi}(V_{\leq k-2}^v, y) \lambda(dy)\right) V_{k-1}^v(dx) \\ &\leq \sum_{k=1}^n \mathbb{E}_t \int \phi_t^x(r) V_{k-1}^v(dx) \leq c_{\leq n-1}^v(t) \phi_t^*(r). \end{aligned}$$

The second inequality follows immediately from the first one, since $E_{\leq n}^v \uparrow E^v$ a.s. as $n \rightarrow \infty$. \square

Denote by $\tau^v := \min(n \in \mathbb{N} : V_n^v = \emptyset)$ the depth of C^v .

Lemma 7.4. *Let $v \in \mathbb{X}$ and $n \in \mathbb{N}$. Then with probability one*

$$d_m(v, V_{\leq n}^v) \leq n E_{\leq n}^v, \quad d_m(v, V^v) \leq \tau^v E^v.$$

Proof. Denote for $\mu \in \mathbf{G}$ and $v_1, v_2 \in \mu$ the minimal length of the paths between v_1 and v_2 within the graph μ by $d^\mu(v_1, v_2)$. Note that for any $k \in \mathbb{N}$ by the triangle inequality, we have

$$d_m(v, V_k^v) = \max_{x \in V_k^v} d(v, x) \leq \max_{x \in V_k^v} d^{C_{\leq k}^v}(v, x) \leq E_1^v + \cdots + E_k^v.$$

Therefore

$$d_m(v, V_{\leq n}^v) = \max(d_m(v, V_1^v), d_m(v, V_2^v), \dots, d_m(v, V_n^v)) \leq E_1^v + \cdots + E_n^v \leq n E_{\leq n}^v.$$

The second inequality follows from the first one by monotone convergence. \square

Proposition 7.5. *Let $v \in \mathbb{X}$, $n \in \mathbb{N}$ and $t, r \geq 0$. Then*

$$\mathbb{P}_t(d_m(v, V_{\leq n}^v) > r) \leq c_{\leq n-1}^v(t) \phi_t^*(r/n), \quad \mathbb{P}_t(d_m(v, V^v) > r) \leq c_{\leq n-1}^v(t) \phi_t^*(r/n) + \mathbb{P}_t(\tau^v > n).$$

Proof. By Lemma 7.4 and Proposition 7.3 we have

$$\mathbb{P}_t(d_m(v, V_{\leq n}^v) > r) \leq \mathbb{P}_t(n E_{\leq n}^v > r) \leq c_{\leq n-1}^v(t) \phi_t^*(r/n).$$

The second inequality follows from the first one and the following inclusion

$$\{d_m(v, V^v) > r\} \subset \{d_m(v, V_{\leq n}^v) > r\} \cup \{\tau^v > n\}.$$

\square

Corollary 7.6. *Let $v \in \mathbb{X}$, $n \in \mathbb{N}$ and $t, r \geq 0$. Then*

$$\mathbb{P}_t(D(V_{\leq n}^v) > r) \leq c_{\leq n-1}^v(t) \phi_t^*(r/2n), \quad \mathbb{P}_t(D(V^v) > r) \leq c_{\leq n-1}^v(t) \phi_t^*(r/2n) + \mathbb{P}_t(\tau^v > n).$$

Proof. The claims follow immediately from Lemma 7.1 and Proposition 7.5. \square

Corollary 7.7. *Let $n \in \mathbb{N}$ and $t \geq 0$. If $D_\varphi^* < \infty$ and $\phi_t^*(r)$ decay exponentially fast as $r \rightarrow \infty$, then there exists $\delta := \delta(t, n) > 0$ such that*

$$\operatorname{ess\,sup}_{v \in \mathbb{X}} \mathbb{E}_t e^{\delta D(V_{\leq n}^v)} < \infty.$$

Proof. The claim follows from Corollaries 7.6 and 6.4. \square

Remark 7.8. Suppose that $\phi_t^*(r)$ and the tail distribution of depth $\mathbb{P}_t(\tau^v > r)$ decay exponentially fast as $r \rightarrow \infty$ with the exponents $\delta_1 > 0$ and $\delta_2 > 0$ respectively. Then using Proposition 7.5 one can easily show that the tail distribution of $d_m(v, V^v)$ decrease as $\exp(-\sqrt{\delta_1 \delta_2 r})$ via r . In other words, using the previous Proposition, we can't prove the light tail property for the diameter of a cluster. We will use a similar construction as in Theorem 6.8 to achieve the desired result; see Theorem 7.9. For example, if $\phi_t^*(r)$ has a heavy-tail (e.g., decay with polynomial speed) and depth τ^v has a light-tailed distribution, then one can build a "better" upper bound for the tail distribution of $d_m(v, V^v)$ using Proposition 7.5.

Theorem 7.9. *Let $h: \mathbb{X} \rightarrow \mathbb{N}$ be a measurable and bounded function and $t \geq 0$. Assume that $D_\varphi^* < \infty$ and $c_h^*(t) := \operatorname{ess\,sup}_{v \in \mathbb{X}} c_{h(v)}^v(t) < 1$. Assume also that $\phi_t^*(r)$ decays exponentially fast as $r \rightarrow \infty$, then there exists $\delta \equiv \delta(t, h^*) > 0$ such that*

$$\operatorname{ess\,sup}_{v \in \mathbb{X}} \mathbb{E}_t e^{\delta D(\widetilde{W}^{v,h})} < \infty.$$

Proof. To describe $W^{v,h}$ and $\widetilde{W}^{v,h}$ we will use the same exploration process (spatial Markov process) $(X_k)_{k \geq 0} = ((Y_k, Z_k))_{k \geq 0}$ as in Theorem 6.8. Recall that $X_0 = (\delta_v, \delta_v)$, $X_1 = (V_{\leq h(v)}^v, V_{h(v)}^v)$ and

$$\begin{aligned} Y_{k+1} &= Y_k + \int \mathbf{1}\{d(v, x) = \min_{y \in Z_k} d(v, y)\} V_{\leq h(x)}^x(\xi_x^k) Z_k(dx), \\ Z_{k+1} &= Z_k + \int \mathbf{1}\{d(v, x) = \min_{y \in Z_k} d(v, y)\} (V_{h(x)}^x(\xi_x^k) - \delta_x) Z_k(dx). \end{aligned}$$

Let $\tau := \min\{k \geq 1 : Z_k = \emptyset\}$. We know that τ is a stopping time w.r.t. $\{Z_k\}_{k \in \mathbb{N}}$, $\tau = |W^{v,h}|$ and $Y_\tau = \widetilde{W}^{v,h}$ in distribution.

Let δ be a positive and sufficiently small parameter. By Lemma 7.1 we have for any $k \geq 1$

$$\begin{aligned} \mathbb{E}_t e^{\delta D(Y_k)} &\leq \mathbb{E}_t \left(e^{\delta D(Y_{k-1})} \mathbb{E}_t \left(\exp \left(\delta \int \mathbf{1}\{d(v, x) = \min_{y \in Z_{k-1}} d(v, y)\} D(V_{\leq h(x)}^x(\xi_x^{k-1})) Z_{k-1}(dx) \right) \middle| X_{k-1} \right) \right) \\ &= \mathbb{E}_t \left(e^{\delta D(Y_{k-1})} \int \mathbf{1}\{d(v, x) = \min_{y \in Z_{k-1}} d(v, y)\} \mathbb{E}_t(e^{\delta D(V_{\leq h(x)}^x(\xi_x^{k-1}))} \middle| Z_{k-1}) Z_{k-1}(dx) \right) \\ &\leq \mathbb{E}_t e^{\delta D(Y_{k-1})} \operatorname{ess\,sup}_{v \in \mathbb{X}} \mathbb{E}_t e^{\delta D(V_{\leq h^*}^v)} \leq \left(\operatorname{ess\,sup}_{v \in \mathbb{X}} \mathbb{E}_t e^{\delta D(V_{\leq h^*}^v)} \right)^k. \end{aligned}$$

By Theorem 6.5 $|\widetilde{W}^{v,h}|$ is a proper random variable. Then, by Fubini's theorem, Cauchy-Schwarz inequality, and the previous inequality, we also have

$$\begin{aligned} \mathbb{E}_t e^{\delta D(\widetilde{W}^{v,h})} &= \mathbb{E}_t \left(e^{\delta D(\widetilde{W}^{v,h})} \sum_{k=1}^{\infty} \mathbf{1}\{\tau = k\} \right) = \sum_{k=1}^{\infty} \mathbb{E}_t (e^{\delta D(Y_k)} \mathbf{1}\{\tau = k\}) \\ &\leq \sum_{k=1}^{\infty} \sqrt{\mathbb{E}_t e^{2\delta D(Y_k)} \mathbb{P}_t(\tau = k)} \leq \sum_{k=1}^{\infty} \sqrt{\left(\operatorname{ess\,sup}_{v \in \mathbb{X}} \mathbb{E}_t e^{2\delta D(V_{\leq h^*}^v)} \right)^k \mathbb{P}_t(\tau = k)}. \end{aligned}$$

Note that $D(V_{\leq h*}^v)$ and τ have light tail distributions uniformly in $v \in \mathbb{X}$ by Corollary 7.7 and Theorem 6.8 respectively. Therefore, we get the required result, since $\lim_{\delta \rightarrow 0} \text{ess sup}_{v \in \mathbb{X}} \mathbb{E}_t e^{2\delta D(V_{\leq h*}^v)} = 1$. \square

Corollary 7.10. *Suppose that $\phi_t^*(r)$ decays exponentially as $r \rightarrow \infty$. Then, under the conditions of Corollary 6.6, there exists $\delta = \delta(t, n) > 0$ such that*

$$\text{ess sup}_{v \in \mathbb{X}} \mathbb{E}_t e^{\delta D(V^v)} < \infty.$$

Proof. The assertion follows from Corollary 5.18 and Theorem 7.9 with $h \equiv n$. \square

Theorem 7.11. *Let $t < t_T$. If $\phi_t^*(r)$ decays exponentially as $r \rightarrow \infty$, then the diameter of the cluster of an arbitrary vertex has a light-tailed distribution (as in Corollary 7.10).*

Proof. We can build the same upper bound for the cluster of an arbitrary vertex as in Theorem 6.10 and then derive the required result with Theorem 7.9. \square

8 The stationary marked RCM

In this section, we consider the stationary RCM as introduced in Section 4. Let $n \in \mathbb{N}$ and define the measurable functions $d_\varphi^{(n)}: \mathbb{M}^2 \rightarrow [0, \infty]$ and $d_\varphi^{[n]}: \mathbb{M}^2 \rightarrow [0, \infty]$ by

$$\begin{aligned} d_\varphi^{(n)}(p, q) &:= \iint \prod_{i=0}^{n-1} \varphi((x_i, p_i), (x_{i+1}, p_{i+1})) d\mathbf{x}_n \mathbb{Q}^{n-1}(d\mathbf{p}_{n-1}), \\ d_\varphi^{[n]}(p, q) &:= \iint \prod_{i=0}^{n-1} \varphi((x_i, p_i), (x_{i+1}, p_{i+1})) \prod_{3 \leq i+2 \leq j \leq n} \bar{\varphi}((x_i, p_i), (x_j, p_j)) d\mathbf{x}_n \mathbb{Q}^{n-1}(d\mathbf{p}_{n-1}). \end{aligned} \quad (8.1)$$

where $p_0 := p$ and $p_n := q$. In the special case $n = 1$, we write

$$d_\varphi(p, q) := d_\varphi^{(1)}(p, q) = \int \varphi(x, p, q) dx.$$

Note that

$$d_\varphi^{(n)}(p, q) := \int \prod_{i=0}^{n-1} d_\varphi(p_i, p_{i+1}) \mathbb{Q}^{n-1}(d\mathbf{p}_{n-1}).$$

It follows from the Mecke equation (3.2) that $t^n d_\varphi^{(n)}(p, \cdot)$ is the \mathbb{Q} -density of the expected number of paths of length n starting in $(0, p)$ and ending in a point with mark in a given set from $\mathcal{B}(\mathbb{M})$. Analogously, $t^n d_\varphi^{[n]}(p, \cdot)$ is the \mathbb{Q} -density of the expected number of *self-avoiding walks* (paths without loops) of length n starting in $(0, p)$ and ending in a point with a mark in a set from $\mathcal{B}(\mathbb{M})$. From the symmetry property of φ we obtain that $d_\varphi^{(n)}$ and $d_\varphi^{[n]}$ are symmetric. From stationarity, one can also notice that for given $n \geq 1$ and $p, q \in \mathbb{M}$ we have

$$d_\varphi^{[2n]}(p, q) \leq \int d_\varphi^{[n]}(p, r) d_\varphi^{[n]}(r, q) \mathbb{Q}(dr). \quad (8.2)$$

For a given measurable $L: \mathbb{M}^2 \rightarrow \mathbb{R} \cup \{\pm\infty\}$ and $r_1, r_2 \in [1, \infty)$, we define the norms

$$\|L\|_{r_1, r_2} := \left(\int \left(\int |L(p, q)|^{r_1} \mathbb{Q}(dp) \right)^{\frac{r_2}{r_1}} \mathbb{Q}(dq) \right)^{\frac{1}{r_2}}, \quad (8.3)$$

$$\|L\|_{\infty, r_2} := \text{ess sup}_{p \in \mathbb{M}} \left(\int |L(p, q)|^{r_2} \mathbb{Q}(dq) \right)^{\frac{1}{r_2}}, \quad (8.4)$$

$$\|L\|_{\infty, \infty} := \text{ess sup}_{p, q \in \mathbb{M}} |L(p, q)|. \quad (8.5)$$

Note that, by definition, we have $D_\varphi^* = \|d_\varphi\|_{\infty,1}$. Take $p \in \mathbb{M}$, $n \in \mathbb{N}$ and $t \geq 0$. By the multivariate Mecke equation, we have that

$$\mathbb{E}_t V_n^{(0,p)}(\mathbb{R}^d \times \cdot) = \int \mathbf{1}\{q \in \cdot\} v_n^{p,q}(t) \mathbb{Q}(dq), \quad (8.6)$$

where the density $v_n^{p,q}(t)$ can be written as a linear combination of integrals similar to those occurring in (8.1). Since we can bound $V_n^{(0,p)}(\mathbb{R}^d \times B)$ by counting all paths of length n without loops and ending in a measurable $B \subset \mathbb{M}$, we have

$$v_n^{p,q}(t) \leq t^n d_\varphi^{[n]}(p, q) \leq t^n d_\varphi^{(n)}(p, q), \quad \mathbb{Q}\text{-a.e. } q \in \mathbb{M} \quad (8.7)$$

and therefore

$$v_n^p(t) := v_n^{(0,p)}(t) \leq t^n \int d_\varphi^{[n]}(p, q) \mathbb{Q}(dq) \leq t^n \int d_\varphi^{(n)}(p, q) \mathbb{Q}(dq). \quad (8.8)$$

We define

$$\Delta_n(t) := c_{\leq n-1}^*(t) + \|v_n(t)\|_{\infty,\infty}, \quad (8.9)$$

where we recall that the first term is the $\|\cdot\|_{\infty}$ -norm of $p \mapsto c_{\leq n-1}^{(0,p)}(t)$ and the second term is defined as the $\|\cdot\|_{\infty,\infty}$ -norm of the function $(p, q) \mapsto v_n^{p,q}(t)$.

Lemma 8.1. *Let $t \geq 0$ and $n \in \mathbb{N}$. If $\|d_\varphi\|_{\infty,1} < \infty$ and $\|d_\varphi^{[n]}\|_{\infty,\infty} < \infty$, then $\Delta_n(t) < \infty$. Moreover, if $\|d_\varphi\|_{\infty,1} < \infty$ and $\|d_\varphi^{[n]}\|_{\infty,2} < \infty$, then $\Delta_{2n}(t) < \infty$.*

Proof. By the recursive structure of $d_\varphi^{(n)}$ we have $\|d_\varphi^{(n)}\|_{\infty,1} \leq \|d_\varphi\|_{\infty,1}^n$. Therefore, we obtain from (8.8) that

$$c_{\leq 2n-1}^*(t) \leq \sum_{k=0}^{2n-1} \|v_k(t)\|_{\infty} \leq 1 + \sum_{k=1}^{2n-1} t^k \|d_\varphi^{(k)}\|_{\infty,1} \leq \frac{(t\|d_\varphi\|_{\infty,1})^{2n} - 1}{t\|d_\varphi\|_{\infty,1} - 1},$$

where the final upper bound has to be interpreted as $2n$ if $t\|d_\varphi\|_{\infty,1} = 1$. On the other hand, we obtain from the inequalities (8.7), (8.2) and the Cauchy–Schwarz inequality,

$$\|v_{2n}(t)\|_{\infty,\infty} \leq t^{2n} \|d_\varphi^{[2n]}\|_{\infty,\infty} \leq t^{2n} \operatorname{ess\,sup}_{p,q \in \mathbb{M}} \int d_\varphi^{[n]}(p, r) d_\varphi^{[n]}(r, q) \mathbb{Q}(dr) \leq t^{2n} \|d_\varphi^{[n]}\|_{\infty,2}^2.$$

Hence

$$\Delta_{2n}(t) \leq \frac{(t\|d_\varphi\|_{\infty,1})^{2n} - 1}{t\|d_\varphi\|_{\infty,1} - 1} + t^{2n} \|d_\varphi^{[2n]}\|_{\infty,\infty} \leq \frac{(t\|d_\varphi\|_{\infty,1})^{2n} - 1}{t\|d_\varphi\|_{\infty,1} - 1} + t^{2n} \|d_\varphi^{[n]}\|_{\infty,2}^2. \quad (8.10)$$

□

Finally, we are ready to state our main result on the strong sharpness of the phase transition, which is a significant generalization of the main result from [37] and some of the results from [3]. The main condition under which we can prove the strong sharpness is that there exists $n \in \mathbb{N}$ satisfying

$$\|d_\varphi\|_{\infty,1} + \|d_\varphi^{[n]}\|_{\infty,\infty} < \infty. \quad (8.11)$$

Theorem 8.2. *Assume that $\|d_\varphi\|_{1,1} > 0$. We have the following:*

- (i) $t_T \geq \|d_\varphi\|_{\infty,1}^{-1}$.

(ii) For $t < t_T$ there exists $\delta_1 := \delta_1(t)$ such that $\text{ess sup}_{p \in \mathbb{M}} \mathbb{E}_t e^{\delta_1 |V^{(0,p)}|} < \infty$.

(iii) If

$$\text{ess sup}_{p \in \mathbb{M}} \int_{\|x\| > u} \varphi(x, p, q) dx \mathbb{Q}(dq)$$

decays exponentially fast as $u \rightarrow \infty$, then for $t < t_T$ there exists $\delta_2 := \delta_2(t)$ such that

$$\text{ess sup}_{p \in \mathbb{M}} \mathbb{E}_t e^{\delta_2 D(V^{(0,p)})} < \infty.$$

(iv) Suppose $n \in \mathbb{N}$ satisfies (8.11). Then $t_T = t_c \in (0, \infty)$ and $\bar{c}_{t_c} = \mathbb{E}_{t_c} \int |V^{(0,p)}| \mathbb{Q}(dp) = \infty$.

(v) Suppose $n \in \mathbb{N}$ satisfies (8.11). Then

$$\|c(t)\|_r \geq \frac{t_c}{\Delta_n(t)(t_c - t)},$$

for $t < t_c$ and for all $r \in [1, \infty]$.

(vi) Suppose that $n \in \mathbb{N}$ satisfies (8.11) and let $\delta > 0$. Then

$$\|\theta(t)\|_r \geq \left(\frac{\bar{\theta}(t_c)}{\delta} + \frac{\mathbf{1}\{\bar{\theta}(t_c) = 0\}}{2t\Delta_n(t)} \right) (t - t_c),$$

for all $t \in [t_c, t_c + \delta]$ and $r \in [1, \infty]$.

Proof. Assertion (i) follows from Lemma 6.1, (ii) follows from Theorem 6.10, (iii) follows from Theorem 7.11. Other claims will be proven later on in this section. More precisely, (iv) follows from Proposition 8.14, Corollary 8.22 and the definition of $t_T^{(1)} = t_c$, (v) follows from Proposition 8.15 and (vi) follows from Theorem 8.21. \square

Remark 8.3. For $n = 1$ the condition (8.11) boils down to $\|d_\varphi\|_{\infty, \infty} < \infty$. This is the main assumption made in [3].

Remark 8.4. Let $k \in \mathbb{N}$. By (8.10) the condition

$$\|d_\varphi\|_{\infty, 1} + \|d_\varphi^{[k]}\|_{\infty, 2} < \infty \tag{8.12}$$

is sufficient for (8.11) with $n = 2k$.

Remark 8.5. Note that if $\phi_t^*(u)$ has a heavy tail in u (thicker than exponential), then the diameter of the cluster of an arbitrary vertex has a heavy tail distribution (thicker than $\phi_t^*(u)$), which can be shown by Proposition 7.5.

8.1 Sufficient condition for non-triviality of the phase transition

We start with the following simple observation.

Proposition 8.6. We have that $t_T^{(1)} \geq \|d_\varphi\|_{2,2}^{-1}$.

Proof. The claim is trivial for $\|d_\varphi\|_{2,2} \in \{0, \infty\}$. Suppose that $\|d_\varphi\|_{2,2} \in (0, \infty)$. Let $n \in \mathbb{N}$. From the Cauchy–Schwarz inequality we have

$$\|d_\varphi^{(n)}\|_{1,2}^2 = \int \left(\int d_\varphi^{(n-1)}(p, q_1) d_\varphi(q_1, q) \mathbb{Q}^2(d(p, q_1)) \right)^2 \mathbb{Q}(dq) \leq \|d_\varphi\|_{2,2}^2 \|d_\varphi^{(n-1)}\|_{1,2}^2.$$

Therefore $\|d_\varphi^{(n)}\|_{1,2} \leq \|d_\varphi\|_{2,2}^n$. On the other hand, we obtain from (8.8) and Jensen’s inequality that

$$\bar{c}_n(t) \leq t^n \|d_\varphi^{(n)}\|_{1,1} \leq t^n \|d_\varphi^{(n)}\|_{1,2}, \quad t > 0.$$

Therefore,

$$\bar{c}(t) = \sum_{n=0}^{\infty} \bar{c}_n(t) \leq \sum_{n=0}^{\infty} t^n \|d_\varphi\|_{2,2}^n,$$

which converges if $t < \|d_\varphi\|_{2,2}^{-1}$. \square

Remark 8.7. Consider the Gilbert graph from Example 4.3 and assume that $\mathbb{Q}\{0\} < 1$. It was proved in [16] that $t_T^{(1)} \in (0, \infty)$ if and only if $q_2 := \int r^{2d} \mathbb{Q}(dr) < \infty$. Note that $q_2 < \infty$ is equivalent to $\|d_\varphi\|_{2,2} > 0$. If $q_2 = \infty$ then it was shown in [16] that $c^{(0,p)}(t) = \infty$ for all $p \geq 0$ and $t > 0$, so that $t_T = t_T^{(1)} = 0$ in this case. The authors of [13] introduce another critical intensity $\hat{t} \leq t_c$ (called $\hat{\lambda}_c$ on p. 3717). If $q_2 < \infty$, then Theorem 2 in this paper shows that $\mathbb{E}_t \lambda_d(Z_0) < \infty$ for all $t < \hat{t}$, where Z_0 denotes the union of all balls $B(x, r)$, $(x, r) \in \eta$, with $0 \in B(x, r)$. Moreover, we then also have

$$\mathbb{E}_t \eta(Z_0 \times [0, \infty)) < \infty, \quad t < \hat{t},$$

Later it was proved in [11] that $t_c = \hat{t}$ provided that $\int r^{5d-3} \mathbb{Q}(dr) < \infty$.

We continue with the following simple fact.

Proposition 8.8. *Suppose $A \in \mathcal{B}(\mathbb{M})$ satisfies $\mathbb{Q}(A) > 0$. Assume that for some symmetric function $\varphi_0: \mathbb{R}^d \rightarrow [0, 1]$, such that $\int \varphi_0(x) dx \in (0, \infty)$, we have*

$$\varphi(x, p, q) \geq \varphi_0(x), \quad \lambda_d \otimes \mathbb{Q}^2\text{-a.e. } (x, p, q) \in \mathbb{R}^d \times A \times A.$$

Then $t_c < \infty$.

Proof. Let ξ' be a RCM driven by $\eta_{\mathbb{R}^d \times A}$ with a connection function φ_0 . It is easy to build a coupling such that $\xi' \subset \xi[\mathbb{R}^d \times A]$. By [34] we know that ξ' percolates for large intensity. Therefore, $t_c < \infty$ for ξ as well. \square

Proposition 8.9. *Assume that $\|d_\varphi\|_{1,1} \in (0, \infty)$, then $t_c < \infty$.*

Proof. Suppose that the mark space contains only two marks $\mathbb{M} = \{p_1, p_2\}$, and a mark cannot directly connect with itself, i.e. $\int \varphi(x, p_i, p_i) dx = 0$ for $i \in \{1, 2\}$ (otherwise we may refer to Proposition 8.8). In this case, we can show $t_c < \infty$ as in [3, Lemma 2.2], whose proof extends the approach from [34] to the marked case. Note that non-triviality of $\|d_\varphi\|_{1,1}$ implies existence of $\varepsilon > 0$, $C \in \mathcal{B}(\mathbb{R}^d)$ and $A, B \in \mathcal{B}(\mathbb{M})$ with $\min\{\lambda_d(C), \mathbb{Q}(A), \mathbb{Q}(B)\} > 0$ such that

$$\varphi(x, p, q) = \varphi(-x, q, p) \geq \varphi_0(x), \quad \lambda_d \otimes \mathbb{Q}^2\text{-a.e. } (x, p, q) \in \mathbb{R}^d \times A \times B,$$

where $\varphi_0(x) := \varepsilon \mathbf{1}\{x \in \pm C\}$. We can again show $t_c < \infty$ by an appropriate coupling ($\xi' \subset \xi[\mathbb{R}^d \times (A \cup B)]$) with the connection function $\varphi_0(x)$ as in Proposition 8.8. \square

Remark 8.10. By definition, we have $D_\varphi^* = \|d_\varphi\|_{\infty,1}$. Therefore, we obtain from Lemma 6.1 that $\|d_\varphi\|_{\infty,1} < \infty$ is equivalent to $t_T > 0$ and hence implies $t_c > 0$. On the other hand, $\|d_\varphi\|_{\infty,1} < \infty$ implies $\|d_\varphi\|_{1,1} < \infty$. Hence, if $0 < \|d_\varphi\|_{\infty,1} < \infty$ then Proposition 8.9 shows that $t_c < \infty$ and hence also $t_T < \infty$. Altogether we see that $0 < \|d_\varphi\|_{\infty,1} < \infty$ is necessary and sufficient for $t_T \in (0, \infty)$, and sufficient for $t_c \in (0, \infty)$.

Remark 8.11. Notice that

$$\|d_\varphi\|_{1,1} \leq \max(\|d_\varphi\|_{\infty,1}, \|d_\varphi\|_{2,2}) \leq \|d_\varphi\|_{\infty,2} \leq \|d_\varphi\|_{\infty,\infty}.$$

Therefore, by Remark 8.4 the condition $\|d_\varphi\|_{\infty,2} < \infty$ is sufficient for (8.11) with $n = 2$.

Example 8.12. Let $\varepsilon > 0$ and consider Example 4.4 with $g(p, q) := (p \vee q)^\varepsilon := \max(p, q)^\varepsilon$. All that follows also applies to $g(p, q) := (p + q)^\varepsilon$ as well, while $p + q \geq p \vee q$. It is easy to see that $\|d_\varphi\|_{\infty,1} < \infty$ if and only if $\varepsilon < 1$. Assume $\varepsilon < 1$ and take $n \in \mathbb{N}$. We have

$$\|d_\varphi^{(n)}\|_{\infty,2}^2 \leq m_\rho^{2n} \int_0^1 \left(\int_0^1 [p_1(p_1 \vee p_2) \cdots (p_{n-1} \vee p_n)]^{-\varepsilon} d\mathbf{p}_{n-1} \right)^2 dp_n.$$

For $\varepsilon < 1/2$ we obtain $\|d_\varphi\|_{\infty,2} < \infty$ from a direct calculation. For $\varepsilon \in [1/2, 1)$, it is also not difficult to show that $\|d_\varphi^{(n)}\|_{\infty,2} < \infty$ if $\varepsilon \in [1 - \frac{1}{2(n-1)}, 1 - \frac{1}{2n})$ for some $n \geq 2$. Therefore $\|d_\varphi^{(2)}\|_{\infty,2} < \infty$ for $\varepsilon = 1/2$ while for $\varepsilon > 1/2$ we have $\|d_\varphi^{(n)}\|_{\infty,2} < \infty$, where $n = \lceil (2 - 2\varepsilon)^{-1} \rceil$. Altogether we obtain for each $\varepsilon \in (0, 1)$ that our condition (8.12) holds. Hence, we have the strong sharp phase transition at $t_c = t_T$.

We note in passing that the condition $\|d_\varphi\|_{2,2} < \infty$ is also equivalent with $\varepsilon < 1$, while condition $\|d_\varphi\|_{1,1} < \infty$ is equivalent with $\varepsilon < 2$.

Remark 8.13. In the case $\varepsilon < 1$, the functions from Example 8.12 are light-tailed versions of the max-kernel and the sum kernel studied, e.g. in [15]. There, the authors focus on the case $\varepsilon \in (1, 2)$, which leads to a power law for the degree distribution. For $\varepsilon < 1$, this distribution has an exponentially decreasing tail. Another example is $g(p, q) = (p \wedge q)^{-\delta} (p \vee q)^\varepsilon$ for given $\delta, \varepsilon > 0$. Then $\|d_\varphi\|_{\infty,1} < \infty$ if and only if $\varepsilon < 1 + \delta$. In this case, g is a light-tailed version of the preferential attachment kernel; see [15]. The sufficient condition $\|d_\varphi\|_{\infty,2} < \infty$ for strong sharpness requires $\varepsilon < 1/2 + \delta$. We conjecture, however, that under the condition $\varepsilon < 1 + \delta$, we have $\|d_\varphi^{(n)}\|_{\infty,2} < \infty$ for some $n = n(\varepsilon, \delta) \in \mathbb{N}$, just as in Example 8.12. Another example is $g(p, q) = |p - q|^\varepsilon$ for some given $\varepsilon > 0$. Then $\|d_\varphi\|_{\infty,1} < \infty$ if and only if $\varepsilon < 1$, while $\|d_\varphi\|_{\infty,2} < \infty$ if and only if $\varepsilon < 1/2$. Again, we believe that, under the condition $\varepsilon < 1$, we have $\|d_\varphi^{(n)}\|_{\infty,2} < \infty$ for some $n = n(\varepsilon) \in \mathbb{N}$. The min kernel and the product kernel from [15] do not satisfy the necessary condition $\|d_\varphi\|_{\infty,1} < \infty$ for strong sharpness.

8.2 Susceptibility mean-field bound

The following Proposition is a refinement of [3, Lemma 2.3] and [8, Proposition 2.1].

Proposition 8.14. Suppose that $n \in \mathbb{N}$ satisfies (8.11). Then $t_T = t_T^{(r)}$ for all $r \in [1, \infty]$.

Proof. We exclude the trivial case $\|d_\varphi\|_{\infty,1} = 0$, since then $t_T = t_T^{(r)} = \infty$. Assume that $\|d_\varphi\|_{\infty,1} > 0$. We only need to show that $t_T = t_T^{(\infty)} \geq t_T^{(1)}$. By Corollary 5.11 we have

$$c^*(t) \leq c_{\leq n-1}^*(t) + \operatorname{ess\,sup}_{p \in \mathbb{M}} \mathbb{E}_t \int \mathbb{E}_t[|V^{(x,q)}(\xi^{[n]})| \mid C_{\leq n}^{(0,p)}] V_n^{(0,p)}(d(x, q)).$$

By the definition of $\xi^{[n]}$ and stationarity, the conditional expectation in the above integral equals $c^{(0,q)}(t)$. Therefore, we obtain from the definition (8.6) of the density $v_n^{p,q}(t)$ that

$$c^*(t) \leq c_{\leq n-1}^*(t) + \operatorname{ess\,sup}_{p \in \mathbb{M}} \int c^{(0,q)}(t) v_n^{p,q}(t) \mathbb{Q}(dq).$$

It follows that $c^*(t) \leq c_{\leq n-1}^*(t) + \bar{c}(t)\|v_n(t)\|_{\infty, \infty}$ and since $\bar{c}(t) \geq 1$ we obtain

$$c^*(t) \leq \Delta_n(t)\bar{c}(t). \quad (8.13)$$

By assumption (8.11) and Lemma 8.1 we have $\Delta_n(t) < \infty$, so that the asserted inequality $t_T \geq t_T^{(1)}$ follows. \square

Proposition 8.15 (Susceptibility mean-field bound). *Suppose $n \in \mathbb{N}$ satisfies (8.11). Then*

$$\|c(t)\|_r \geq \frac{t_T}{\Delta_n(t)(t_T - t)} \quad (8.14)$$

for $t < t_T$ and for all $r \in [1, \infty]$.

Proof. To prove this result, we need to recall some of the notation from [3]. Define

$$T_t(p, q) = \int \mathbb{P}_t((0, p) \leftrightarrow (x, q) \text{ in } \xi^{(0, p), (x, q)}) dx$$

and let the integral operator \mathcal{T}_t act as $(\mathcal{T}_t f)(p) = \int T_t(p, q) f(q) \mathbb{Q}(dq)$, for every square-integrable function f on \mathbb{M} (with respect to the probability measure \mathbb{Q}). Let $t_o = \inf\{t > 0 : \|\mathcal{T}_t\|_{op} = \infty\}$, where, as usual, $\|\cdot\|_{op}$ refers to the operator norm for a linear operator on a Banach space.

By [3, Lemma 2.3] (which applies without Assumption D from that paper) and Proposition 8.14 we have $t_o = t_T$. From [8, Lemma 3.2], we know $\|\mathcal{T}_t\|_{op} \leq \|T_t\|_{\infty, 1}$ (this is proven by Schur's test). Since $c^{(0, p)}(t) = 1 + t \int T_t(p, q) \mathbb{Q}(dq)$ we have $c^*(t) = 1 + t\|T_t\|_{\infty, 1}$. By [3, Theorem 2.5] (which again does not require Assumption D) we have $\|\mathcal{T}_t\|_{op} \geq (t_o - t)^{-1}$ for $t \in (0, t_o)$. Hence $\|T_t\|_{\infty, 1} \geq (t_T - t)^{-1}$ and $c^*(t) \geq t_T(t_T - t)^{-1}$ for $t \in (0, t_T)$. For $r = 1$, the asserted result now follows from the inequality (8.13). The general case $r \geq 1$ follows from Hölder's inequality. \square

8.3 Strong sharpness of the phase transition

Analogously to [3], we introduce a continuous and mark-dependent analogy of the magnetization originally introduced by Aizenman and Barsky [1]. Let $\gamma \in (0, 1)$ be a parameter with which we enrich the marked RCM by adding to each vertex a uniform $(0, 1)$ (Lebesgue) label (independent of everything else), and let $\mathbb{P}_{t, \gamma}$ denote the resulting probability measure. A vertex $x \in \eta$ is called a *ghost* vertex if its label is at most γ , and we write $x \in \mathcal{G}$. Similarly, we write $x \leftrightarrow \mathcal{G}$ if x is connected to a ghost vertex. We define magnetization as follows

$$M(t, \gamma, p) := \mathbb{P}_{t, \gamma}((0, p) \leftrightarrow \mathcal{G} \text{ in } \xi^{(0, p)}). \quad (8.15)$$

In accordance with our previous notation, we use the $L^r(\mathbb{Q})$ -norms for $r \in [1, \infty]$ to define

$$\bar{M}(t, \gamma) := \|M(t, \gamma, \cdot)\|_1, \quad M^*(t, \gamma) := \|M(t, \gamma, \cdot)\|_\infty. \quad (8.16)$$

Recall the definition of ξ^{Q_0} and C^{Q_0} in Subsection 4.2. We assume that Q_0 is also independent of the labels. Note that $\bar{M}(t, \gamma) = \mathbb{P}_{t, \gamma}((0, Q_0) \leftrightarrow \mathcal{G} \text{ in } \xi^{Q_0})$. We will also need the following functions. For $t \in \mathbb{R}_+$, we define

$$\bar{c}_f(t) := \mathbb{E}_t |C^{Q_0}| \mathbf{1}\{|C^{Q_0}| < \infty\} = \sum_{n \in \mathbb{N}} n \mathbb{P}_t(|C^{Q_0}| = n), \quad (8.17)$$

and for $\gamma \in (0, 1)$ we also define the “ghost-free” mean size of the cluster of a typical vertex

$$\bar{c}(t, \gamma) = \mathbb{E}_{t, \gamma} |C^{Q_0}| \mathbf{1}\{C^{Q_0} \cap \mathcal{G} = \emptyset\}. \quad (8.18)$$

It is easy to relate the above function to the mean size of the finite cluster of a typical vertex and the percolation probability $\bar{\theta}(t) = \mathbb{P}_{t, \gamma}(|C^{Q_0}| = \infty)$.

Lemma 8.16. *Let $t \in \mathbb{R}_+$. Then*

$$\lim_{\gamma \rightarrow 0} \bar{M}(t, \gamma) = \bar{\theta}(t), \quad \lim_{\gamma \rightarrow 0} \bar{c}(t, \gamma) = \bar{c}_f(t).$$

Proof. The proof is direct and follows the same lines as in [3]. For $\gamma \in (0, 1)$ we have

$$\begin{aligned} \bar{M}(t, \gamma) &= 1 - \mathbb{P}_{t, \gamma}((0, Q_0) \leftrightarrow \mathcal{G} \text{ in } \xi^{Q_0}) = 1 - \sum_{n \in \mathbb{N}} \mathbb{P}_{t, \gamma}(C^{Q_0} \cap \mathcal{G} = \emptyset, |C^{Q_0}| = n) \\ &= 1 - \sum_{n \in \mathbb{N}} (1 - \gamma)^n \mathbb{P}_t(|C^{Q_0}| = n) = 1 - \mathbb{E}_t(1 - \gamma)^{|C^{Q_0}|}. \end{aligned} \quad (8.19)$$

Letting $\gamma \rightarrow 0$, we obtain the first result from monotone convergence. It is also easy to see that the function $\gamma \mapsto \bar{M}(t, \gamma)$ is analytic on $(0, 1)$ for all $t \in \mathbb{R}_+$.

For $\gamma > 0$ we obtain from our independence assumption that $|C^{Q_0}| < \infty$ a.s. on the event $\{C^{Q_0} \cap \mathcal{G} = \emptyset\}$. We then have

$$\begin{aligned} \bar{c}(t, \gamma) &= \sum_{n \in \mathbb{N}} n \mathbb{P}_{t, \gamma}(|C^{Q_0}| = n, C^{Q_0} \cap \mathcal{G} = \emptyset) \\ &= \sum_{n \in \mathbb{N}} n (1 - \gamma)^n \mathbb{P}_t(|C^{Q_0}| = n). \end{aligned} \quad (8.20)$$

As $\gamma \rightarrow 0$, we obtain the second result from monotone convergence. \square

We will also need the following lemma on differential inequalities for the magnetization.

Lemma 8.17 (Aizenman-Barsky differential inequalities on the magnetization). *Let $\gamma \in (0, 1)$ and $t > 0$ and assume that $\|d_\varphi\|_{\infty, 1} < \infty$. Then we have*

$$\begin{aligned} \text{(i)} \quad & \frac{\partial \bar{M}(t, \gamma)}{\partial t} \leq \frac{1 - \gamma}{t} M^*(t, \gamma) \frac{\partial \bar{M}(t, \gamma)}{\partial \gamma}. \\ \text{(ii)} \quad & \bar{M}(t, \gamma) \leq \gamma \frac{\partial \bar{M}(t, \gamma)}{\partial \gamma} + \|M(t, \gamma)\|_2^2 + t M^*(t, \gamma) \frac{\partial \bar{M}(t, \gamma)}{\partial t}. \end{aligned}$$

Proof. The results follow from the Leibniz differentiation rule and [3, Lemma 3.8]. \square

Lemma 8.18. *Let $t \in \mathbb{R}_+$, $n \in \mathbb{N}$ and $\gamma \in (0, 1)$. Then*

$$M^*(t, \gamma) \leq \Delta_n(t) \bar{M}(t, \gamma). \quad (8.21)$$

Proof. If $\Delta_n(t) = \infty$ or $\|d_\varphi\|_{\infty, 1} = 0$, then inequality (8.21) is trivial. Therefore, we can assume that $\Delta_n(t) < \infty$ and $\|d_\varphi\|_{\infty, 1} > 0$. Fix $p \in \mathbb{M}$. We have

$$\begin{aligned} M(t, \gamma, p) &= \mathbb{P}_{t, \gamma}((0, p) \leftrightarrow \mathcal{G} \text{ in } \xi^{(0, p)}) = \mathbb{P}_{t, \gamma} \left(\bigcup_{k \geq 0} \{C_k^{(0, p)} \cap \mathcal{G} \neq \emptyset\} \right) \\ &\leq \mathbb{P}_{t, \gamma} \left(C_{\leq n-1}^{(0, p)} \cap \mathcal{G} \neq \emptyset \right) + \mathbb{P}_{t, \gamma} \left(C_{\geq n}^{(0, p)} \cap \mathcal{G} \neq \emptyset \right) \\ &= 1 - \mathbb{E}_t(1 - \gamma)^{|C_{\leq n-1}^{(0, p)}|} + \mathbb{P}_{t, \gamma} \left(C_{\geq n}^{(0, p)} \cap \mathcal{G} \neq \emptyset \right) \\ &\leq \gamma c_{\leq n-1}^{(0, p)}(t) + \mathbb{E}_{t, \gamma} \int \mathbf{1}\{(x, q) \leftrightarrow \mathcal{G} \text{ in } C_{\geq n}^{(0, p)}\} C_n^{(0, p)}(d(x, q)), \end{aligned}$$

where we have used the Bernoulli inequality for the last line. To treat the above second term I_2 , say, we let $D_{\leq n}^{(0, p)}$ denote the graph $C_{\leq n}^{(0, p)}$, where all points (vertices) are marked by their labels, except those of $C_n^{(0, p)}$. Then

$$I_2 = \mathbb{E}_{t, \gamma} \int \mathbb{P}((x, q) \leftrightarrow \mathcal{G} \text{ in } C_{\geq n}^{(0, p)} \mid D_{\leq n}^{(0, p)}) C_n^{(0, p)}(d(x, q)).$$

By the spatial Markov property (in fact, we need the more refined [4, Theorem 7.1]) and stochastic monotonicity (as in Corollary 5.11) the conditional probability occurring above can be bounded by $M(t, \gamma, p)$. Therefore,

$$I_2 \leq \mathbb{E}_t \int M(t, \gamma, q) C_n^{(0,p)}(d(x, q)) = \int M(t, \gamma, q) v_n^{p,q}(t) \mathbb{Q}(dq) \leq \bar{M}(t, \gamma) \|v_n(t)\|_{\infty, \infty},$$

where the equality comes directly from the definition of the densities $v_n^{p,q}(t)$. Since $\gamma \leq \bar{M}(t, \gamma)$ we obtain the assertion. \square

Lemma 8.19. *Let $t \in \mathbb{R}_+$, $n \in \mathbb{N}$, $\gamma \in (0, 1)$ and assume that $\bar{c}_f(t) = \infty$. Then*

$$\bar{M}(t, \gamma) \geq \sqrt{\frac{\gamma}{\Delta_n(t) + (\Delta_n(t))^2}} \geq \sqrt{\frac{\gamma}{2}} \frac{1}{\Delta_n(t)}. \quad (8.22)$$

Proof. We proceed similarly to the proof of [3, Corollary 3.11]. If $\Delta_n(t) = \infty$, then the inequality (8.22) is trivial. Assume that $\Delta_n(t) < \infty$ and $\|d_\varphi\|_{\infty, 1} > 0$. Then we can use the preceding lemmas. Inserting the first inequality of Lemma 8.17, and using simple observation $\|M(t, \gamma)\|_2^2 \leq M^*(t, \gamma) \bar{M}(t, \gamma)$ we obtain

$$\bar{M}(t, \gamma) \leq \gamma \frac{\partial \bar{M}(t, \gamma)}{\partial \gamma} + M^*(t, \gamma) \bar{M}(t, \gamma) + (1 - \gamma)(M^*(t, \gamma))^2 \frac{\partial \bar{M}(t, \gamma)}{\partial \gamma}.$$

Then by Lemma 8.18 we get

$$\bar{M}(t, \gamma) \leq \gamma \frac{\partial \bar{M}(t, \gamma)}{\partial \gamma} + \Delta_n(t) \bar{M}(t, \gamma)^2 + (1 - \gamma) \Delta_n^2(t) \bar{M}(t, \gamma)^2 \frac{\partial \bar{M}(t, \gamma)}{\partial \gamma}. \quad (8.23)$$

In the remainder of the proof, we fix t and drop this argument from our notation. By (8.19) the function M (given by $\gamma \mapsto M(\gamma) := \bar{M}(t, \gamma)$) is strictly increasing and therefore has a differentiable inverse M^{-1} . Then we can rewrite (8.23) for all x in the range of M as

$$x \leq \frac{M^{-1}(x)}{(M^{-1})'(x)} + \Delta_n x^2 + (1 - M^{-1}(x)) \frac{\Delta_n^2 x^2}{(M^{-1})'(x)}. \quad (8.24)$$

We have $\frac{d}{dx}(x^{-1} M^{-1}(x)) = x^{-1} (M^{-1})'(x) - x^{-2} M^{-1}(x)$. Multiplying (8.24) by $x^{-2} (M^{-1})'(x)$ we therefore obtain

$$\frac{d}{dx}(x^{-1} M^{-1}(x)) \leq \Delta_n (M^{-1})'(x) + (1 - M^{-1}(x)) \Delta_n^2 \leq \Delta_n (M^{-1})'(x) + \Delta_n^2.$$

We wish to integrate this inequality on $[0, y]$ for some y in the range of M . To do so, we note that $M^{-1}(0) = 0$ and

$$\lim_{x \rightarrow 0} \frac{M^{-1}(x)}{x} = (M^{-1})'(0) = \frac{1}{M'(0)} = \frac{1}{\bar{c}_f(t)} = 0,$$

where the penultimate identity follows from (8.19) and the final one from our assumption $c_f(t) = \infty$. Therefore, we obtain

$$y^{-1} M^{-1}(y) \leq \Delta_n M^{-1}(y) + \Delta_n^2 y,$$

that is $\gamma / \bar{M}(t, \gamma) \leq \Delta_n(t) \gamma + \Delta_n(t)^2 \bar{M}(t, \gamma)$ for each $\gamma > 0$. Since $\gamma \leq \bar{M}(t, \gamma)$, the first inequality in (8.22) follows. The second is then a consequence of $\Delta_n(t) \geq 1$, which is true by definition. \square

Proposition 8.20. *Let $t > t_T^{(1)}$ and $n \in \mathbb{N}$. If $\bar{\theta}(t_T^{(1)}) = 0$, then*

$$\bar{\theta}(t) \geq \frac{t - t_T^{(1)}}{2t \Delta_n(t)}. \quad (8.25)$$

Proof. Note that if $\Delta_n(t) = \infty$, then the inequality (8.25) is trivial. Suppose that $\Delta_n(t) < \infty$ and $\|d_\varphi\|_{\infty,1} > 0$. Then we have by Proposition 8.14 that $t_T = t_T^{(1)} = t_T^{(\infty)}$. Let $t' > t_T$ and $t \in (t_T, t']$. Multiplying the second inequality of Lemma 8.17 by $\gamma^{-1}\bar{M}(t, \gamma)^{-1}$ and using simple observation $\|M(t, \gamma)\|_2^2 \leq M^*(t, \gamma)\bar{M}(t, \gamma)$ gives

$$\frac{1}{\gamma} \leq \frac{1}{\bar{M}(t, \gamma)} \frac{\partial \bar{M}(t, \gamma)}{\partial \gamma} + \frac{M^*(t, \gamma)}{\gamma} + \frac{tM^*(t, \gamma)}{\gamma \bar{M}(t, \gamma)} \frac{\partial \bar{M}(t, \gamma)}{\partial t}.$$

By Lemma 8.18 we get

$$\begin{aligned} \frac{1}{\gamma} &\leq \frac{1}{\bar{M}(t, \gamma)} \frac{\partial \bar{M}(t, \gamma)}{\partial \gamma} + \frac{\Delta_n(t)\bar{M}(t, \gamma)}{\gamma} + \frac{t\Delta_n(t)}{\gamma} \frac{\partial \bar{M}(t, \gamma)}{\partial t} \\ &\leq \frac{1}{\bar{M}(t, \gamma)} \frac{\partial \bar{M}(t, \gamma)}{\partial \gamma} + \frac{\Delta_n(t')}{\gamma} \left(\bar{M}(t, \gamma) + t \frac{\partial \bar{M}(t, \gamma)}{\partial t} \right) \\ &= \frac{\partial \log(\bar{M}(t, \gamma))}{\partial \gamma} + \frac{\Delta_n(t')}{\gamma} \frac{\partial}{\partial t} (t\bar{M}(t, \gamma)). \end{aligned}$$

We now integrate the above inequality over $(t, \gamma) \in [t_T, t'] \times [\gamma_1, \gamma_2]$, where $0 < \gamma_1 \leq \gamma_2 < 1$. Since all the integrands are non-negative, we can use Fubini's theorem to exchange the order of the integrals, and we will also use the properties of the function $\bar{M}(t, \gamma)$, i.e. non-negativity and increasing in t and γ . Therefore

$$\begin{aligned} (t' - t_T) \log(\gamma_2/\gamma_1) &\leq \int_{t_T}^{t'} \log(\bar{M}(t, \gamma_2)/\bar{M}(t, \gamma_1)) dt + \Delta_n(t') \int_{\gamma_1}^{\gamma_2} \frac{1}{\gamma} (t' \bar{M}(t', \gamma) - t_T \bar{M}(t_T, \gamma)) d\gamma \\ &\leq (t' - t_T) \log(\bar{M}(t', \gamma_2)/\bar{M}(t_T, \gamma_1)) + \Delta_n(t') t' \bar{M}(t', \gamma_2) \log(\gamma_2/\gamma_1). \end{aligned}$$

Dividing by $\log(\gamma_2/\gamma_1)$ we get

$$t' - t_T \leq (t' - t_T) \left(\frac{\log(\bar{M}(t', \gamma_2))}{\log(\gamma_2) - \log(\gamma_1)} - \frac{\log(\bar{M}(t_T, \gamma_1))}{\log(\gamma_2) - \log(\gamma_1)} \right) + \Delta_n(t') t' \bar{M}(t', \gamma_2). \quad (8.26)$$

Since $\bar{\theta}(t_T) = 0$, the cluster of a typical vertex is finite almost surely. Therefore $\bar{c}_f(t_T) = \mathbb{E}_{t_T}[C^{Q_0}]$. Moreover, letting $t \uparrow t_T$ in (8.14), we obtain $\bar{c}(t_T) = \infty$. By Lemma 8.19 we have for $0 < \gamma_1 < \gamma_2$ that

$$-\frac{\log(\bar{M}(t_T, \gamma_1))}{\log(\gamma_2) - \log(\gamma_1)} \leq \frac{\log(\sqrt{2}\Delta_n(t_T)) - \frac{1}{2}\log(\gamma_1)}{\log(\gamma_2) - \log(\gamma_1)}.$$

As $\gamma_1 \rightarrow 0$, the above right-hand side tends to $\frac{1}{2}$. Hence it follows from (8.26) that

$$\bar{M}(t', \gamma_2) \geq \frac{t' - t_T}{2t' \Delta_n(t')}.$$

Letting $\gamma_2 \rightarrow 0$ and using Lemma 8.16 concludes the proof. \square

Theorem 8.21 (Percolation mean-field bound). *Let $\delta > 0$. Suppose that $n \in \mathbb{N}$ satisfies (8.11). Then*

$$\|\theta(t)\|_r \geq \left(\frac{\bar{\theta}(t_T)}{\delta} + \frac{\mathbf{1}\{\bar{\theta}(t_T) = 0\}}{2t\Delta_n(t)} \right) (t - t_T), \quad (8.27)$$

for all $t \in [t_T, t_T + \delta]$ and $r \in [1, \infty]$.

Proof. By Hölder's inequality, we get $\|\theta(t)\|_r \geq \|\theta(t)\|_1 \equiv \bar{\theta}(t)$ for all $r \in [1, \infty]$. If $\bar{\theta}(t_T) > 0$, then the result follows from the monotonicity of $\bar{\theta}(t)$. Otherwise, the result follows from Proposition 8.20. \square

Corollary 8.22 (Sharpness of phase transition). *Under the assumptions of Proposition 8.14, we have $t_c = t_T$.*

Proof. As already noticed in Section 4 we always have $t_T \leq t_c$. Let $t > t_T$. By Theorem 8.21 there exists $A \in \mathcal{B}(\mathbb{M})$ with $\mathbb{Q}(A) > 0$ and $\theta^p(t) > 0$ for all $p \in A$. Therefore $t \geq t_c$ and hence $t_T \geq t_c$. \square

Remark 8.23. Let us consider here the hyperbolic counterpart of the stationary marked RCM; see [7]. In this case $\mathbb{X} := \mathbb{H}^d \times \mathbb{M}$, where \mathbb{H}^d is the d -dimensional hyperbolic space (with $d \geq 2$) as in Example 6.11 and \mathbb{M} is as before. Assume that $\lambda = \mathcal{H}^d \otimes \mathbb{Q}$, where \mathcal{H}^d denotes the Haar measure on \mathbb{R}^d and \mathbb{Q} is a probability measure on \mathbb{M} , also as before. Assume that the connection function is given by $\varphi((x, p), (y, q)) = \tilde{\varphi}(d_{\mathbb{H}^d}(x, y), p, q)$ for some measurable $\tilde{\varphi}: \mathbb{R}_+ \times \mathbb{M}^2 \rightarrow [0, 1]$ such that $\tilde{\varphi}(x, \cdot)$ is symmetric for all $x \in \mathbb{H}^d$. Fix a point $o \in \mathbb{H}^d$. Since the space \mathbb{H}^d is homogeneous, we can argue as in Remark 4.1 to see that

$$t_c = \sup\{t \geq 0 : \mathbb{P}_t(|C^{(o,p)}| < \infty) = 0 \text{ for } \mathbb{Q}\text{-a.e. } p\}, \quad t_T = \sup\{t \geq 0 : \operatorname{ess\,sup}_{p \in \mathbb{M}} \mathbb{E}_t |C^{(o,p)}| < \infty\}.$$

Define $d_{\tilde{\varphi}}(p, q) = \int \tilde{\varphi}(d_{\mathbb{H}^d}(x, y), p, q) \mathcal{H}^d(dx)$ for $(p, q) \in \mathbb{M}^2$. Most of the results of this section remain true in this setting, provided our assumptions are suitably modified (replacement of d_{φ} by $d_{\tilde{\varphi}}$). Indeed, the geometry of the ambient space \mathbb{R}^d does not enter most of our arguments. One exception is Proposition 8.9. However, we believe that, under the assumption $\|d_{\tilde{\varphi}}\|_{1,1} < \infty$, the proof of [9, Proposition 1.1] can be extended to the marked case, just as in the Euclidean marked case. We would then obtain that our condition (8.11) (with hyperbolic $d_{\tilde{\varphi}}$) implies the strong sharp phase transition at $t_T = t_c \in (0, \infty)$, just as in the marked stationary Euclidean case. Thanks to [9, Proposition 1.1] the condition from Proposition 8.8 is sufficient for $t_c < \infty$.
