

Stochastic Dominance Constrained Optimization with S-shaped Utilities: Poor-Performance-Region Algorithm and Neural Network

Zeyun Hu*

Yang Liu†

Abstract

We investigate the static portfolio selection problem of S-shaped and non-concave utility maximization under first-order and second-order stochastic dominance (SD) constraints. In many S-shaped utility optimization problems, one should require a liquidation boundary to guarantee the existence of a finite concave envelope function. A first-order SD (FSD) constraint can replace this requirement and provide an alternative for risk management. We explicitly solve the optimal solution under a general S-shaped utility function with a first-order stochastic dominance constraint. However, the second-order SD (SSD) constrained problem under non-concave utilities is difficult to solve analytically due to the invalidity of Sion's maxmin theorem. For this sake, we propose a numerical algorithm to obtain a plausible and sub-optimal solution for general non-concave utilities. The key idea is to detect the poor performance region with respect to the SSD constraints, characterize its structure and modify the distribution on that region to obtain (sub-)optimality. A key financial insight is that the decision maker should follow the SD constraint on the poor performance scenario while conducting the unconstrained optimal strategy otherwise. We provide numerical experiments to show that our algorithm effectively finds a sub-optimal solution in many cases. Finally, we develop an algorithm-guided piecewise-neural-network framework to learn the solution of the SSD problem, which demonstrates accelerated convergence compared to standard neural network approaches.

Keywords: Non-concave utility, portfolio selection, risk constraints, first-order stochastic dominance (FSD), second-order stochastic dominance (SSD), numerical method, neural network

1 Introduction

S-shaped utility functions, formalized in cumulative prospect theory ([Tversky and Kahneman \(1992\)](#)) and surveyed in behavioral finance ([Barberis and Thaler \(2003\)](#)), capture two salient features of investor behavior: risk seeking in losses and risk aversion in gains. In portfolio selection problems, this non-concavity can induce aggressive tail-risk taking ([Carpenter \(2000\)](#); [He and Kou \(2018\)](#); [Liang and Liu \(2020\)](#)). In

particular, when the pricing kernel has a heavy right tail, unconstrained S-shaped optimization typically generates a heavy left tail in terminal wealth, leading to large probabilities of extreme losses, which are the risks that classical VaR/ES-type constraints do not reliably mitigate.

We adopt stochastic dominance (SD) constraints as an implementable approach to control such downside risk under non-concave utilities. First-order SD (FSD) relative to a benchmark wealth X_0 enforces a quantile-by-quantile floor, offering a distribution-level safety guarantee that often aligns better with practice than hard liquidation boundaries. Second-order SD (SSD) controls cumulative quantiles, providing a flexible, model-free form of downside protection from the pathological risk-seeking induced by the convex (loss) region of S-shaped preferences.

Analytically, SD-constrained utility maximization is well understood for strictly concave utilities via quantile reformulations, duality, and saddle-point arguments (Föllmer and Schied (2016); Wang and Xia (2021)). However, extending these tools to non-concave utilities under SSD is challenging. Sion’s max-min theorem no longer applies in the key saddle-point step, concavification is not guaranteed to be valid because optimizers can fall in regions where the utility and its concave envelope differ (Liang and Liu (2024)), and closed-form solutions are scarce beyond special, technically constrained settings (Wang and Xia (2021)). This paper contributes on three aspects.

First, we derive an explicit optimal solution for portfolio selection with a general S-shaped utility under an FSD constraint relative to a benchmark. Crucially, the FSD constraint obviates the need for a liquidation boundary: the optimal wealth is counter-comonotone with the pricing kernel and exhibits a two-regime structure, coinciding with the classical solution in favorable states and binding to the benchmark quantile in adverse states. This clarifies how FSD serves as a “soft” and interpretable left-tail boundary.

Second, we propose the Poor-Performance-Region Algorithm (PPRA), a numerical method that constructs a feasible, high-quality suboptimal solution, and in many cases a numerically optimal one. The key idea is to identify the “poor performance region”, namely quantile levels where the unconstrained classical optimizer violates SSD relative to the benchmark. The algorithm partitions this region and applies a state-dependent correction to enforce SSD, while reverting to the unconstrained policy elsewhere. Financially, the resulting rule is intuitive: track the benchmark in poor states to satisfy SSD; otherwise follow the classical optimizer.

Third, we develop an algorithm-guided piecewise-neural-network framework that embeds the PPRA-derived partition and analytic priors into the architecture. This design drastically narrows the functional search space, accelerates convergence, satisfies budget and SSD constraints more quickly, and attains higher objective values than a standard monolithic network, especially in non-concave settings where regular training struggles with infeasibility and local minima.

Methodologically, our approach combines duality and concavification insights (Karatzas et al. (1987); Carpenter (2000); Liang and Liu (2020)) with the quantile formulation of utility maximization (He and Zhou (2011); Föllmer and Schied (2016)) and SD theory (Wang and Xia (2021); Wang, Wei and Xia (2024)). For FSD, we provide a closed-form solution without a liquidation boundary and interpret FSD as a distributional

safety floor. For SSD, we translate feasibility into integral inequalities in the quantile domain and design a correction that “repairs” exactly where the unconstrained policy underperforms the benchmark.

We validate our methods in a complete-market (Black-Scholes) setting across diverse utilities (CRRA, exponential, log, S-shaped, and piecewise) and benchmarks (log-normal, normal, exponential, uniform). For FSD, the explicit solution confirms that dominance constraints can substitute for liquidation boundaries. For SSD, PPRA consistently produces feasible, interpretable solutions that often match known optima in concave cases. The piecewise neural network guided by PPRA converges substantially faster and to better solutions than a monolithic network, particularly under non-concavity.

Financial implications are immediate. First, FSD guarantees that all terminal-wealth quantiles exceed those of a benchmark, giving a realistic and implementable floor. Second, the optimal/near-optimal policy is to adhere to the benchmark in bad states and follow the classical policy otherwise, yielding transparent risk management. Third, SD constraints significantly reduce the probability of extreme losses induced by S-shaped preferences, beyond what standard VaR/ES controls typically achieve.

Scope and limitations. Our analysis focuses on complete markets and static terminal-wealth problems, leveraging their equivalence to dynamic continuous-time settings via the pricing kernel. While PPRA is broadly applicable and robust in experiments, it provides suboptimality guarantees rather than universal optimality in the non-concave SSD case; establishing general sharp optimality conditions remains a promising direction for future research.

The structure of this paper is as follows. Section 2 presents the model. Section 3 derives the explicit FSD solution for general S-shaped utilities and explains how FSD replaces liquidation boundaries. Section 4 explains the analytical hurdles of SSD under non-concavity and introduces PPRA. Section 5 provides numerical studies across utilities and benchmarks. Section 6 develops the algorithm-guided, piecewise neural-network framework and contrasts it with standard networks. Section 7 concludes.

2 Model Settings

Fix an atomless probability space $(\Omega, \mathcal{F}, \mathbb{P})$. Let L^0 be the set of all random variables on $(\Omega, \mathcal{F}, \mathbb{P})$. Let $L^1 \subset L^0$ be the set of all integrable random variables. Denote the pricing kernel by a continuously-distributed random variable $\rho : \Omega \rightarrow (0, \infty)$ and $\rho \in L^1$. For an initial capital $\bar{x} \in \mathbb{R}$, the static version of the classic Merton (1969)’s problem is given by

$$\max_{X \in L^0} \mathbb{E}[U(X)] \text{ s.t. } \mathbb{E}[\rho X] \leq \bar{x}, \quad (1)$$

where $U : \mathbb{R} \rightarrow \mathbb{R}$ is a utility function to be specified in the following different sections. The constraint is called the budget constraint. For a strictly concave utility, the solution of Problem (1) is given by

$$X_{\text{cla}} = I(\lambda_{\text{cla}} \rho), \quad (2)$$

where the conjugate function $I : (0, \infty) \rightarrow \mathbb{R}$ is given by $I(y) \triangleq \arg \sup_{x \in \mathbb{R}} [U(x) - xy]$, $y > 0$ (We will revisit the definition if U is non-concave) and $\lambda_{\text{cla}} > 0$ is a Lagrange multiplier solved from $\mathbb{E}[\rho I(\lambda_{\text{cla}} \rho)] = \bar{x}$. The problem (1) can be seen as the terminal wealth optimization of the classic continuous-time Merton's problem in a complete market; see Appendix A of [Liang and Liu \(2024\)](#) for details. In the classic Merton's problem, the utility function is chosen as a smooth and strictly concave function, including power/log (CRRA, constant relative risk aversion) or exponential (CARA, constant absolute risk aversion) functions.

Now we introduce the concept of stochastic dominance (SD). For a random variable $X \in L^0$, the (upper) quantile function $Q_X : [0, 1] \rightarrow \mathbb{R} \cup \{\pm\infty\}$ is defined by

$$Q_X(s) = \inf\{x \in \mathbb{R} \mid \mathbb{P}(X \leq x) > s\}, \quad s \in [0, 1].$$

Denote by \mathcal{Q} the set of all quantile functions:

$$\mathcal{Q} \triangleq \{Q : [0, 1] \rightarrow \mathbb{R} \cup \{\pm\infty\} \mid Q \text{ is increasing and right-continuous}\}.$$

Definition 1 (Stochastic dominance). (1) Fix $X, Y \in L^0$. X is greater than Y in first-order stochastic dominance (FSD) if $Q_X(s) \geq Q_Y(s)$ for all $s \in (0, 1)$, which is denoted by $X \succeq_{(1)} Y$.

(2) Fix $X, Y \in L^1$. X is greater than Y in second-order stochastic dominance (SSD) if $\int_0^t Q_X(s) ds \geq \int_0^t Q_Y(s) ds$ for all $t \in (0, 1)$, which is denoted by $X \succeq_{(2)} Y$.

We specify a given benchmark wealth $X_0 \in L^0$. We proceed to study the problem with the first-order stochastic dominance (FSD) or second-order stochastic dominance (SSD) constraints:

$$(\text{FSD Problem}) \quad \max_{X \in L^0} \mathbb{E}[U(X)] \text{ s.t. } \mathbb{E}[\rho X] \leq \bar{x} \text{ and } X \succeq_{(1)} X_0, \quad (3)$$

and

$$(\text{SSD Problem}) \quad \max_{X \in L^1} \mathbb{E}[U(X)] \text{ s.t. } \mathbb{E}[\rho X] \leq \bar{x} \text{ and } X \succeq_{(2)} X_0. \quad (4)$$

We denote the quantile function of X_0 by $Q_0 \in \mathcal{Q}$. Further, we define a minimal budget value:

$$x_{Q_0} \triangleq \mathbb{E}[\rho X_0] = \int_0^1 Q_0(s) Q_\rho(1-s) ds.$$

Throughout, we assume $\bar{x} \geq x_{Q_0}$. As a result, both problems (3)-(4) have at least one feasible solution X_0 .

[Wang and Xia \(2021\)](#) propose and solve the FSD and SSD problems (3)-(4) with smooth and concave utilities; see [Wang, Wei and Xia \(2024\)](#) for a mean-stochastic-dominance problem. In the following, we investigate the corresponding general non-concave utility optimization, particularly, S-shaped utility optimization.

3 FSD Problem and Analytical Solution

In this section, we apply the general S-shaped utility in Definition 2 (see Liang and Liu (2020)) and proceed to study Problem (3). Now we define a general S-shaped utility function U .

Definition 2 (General S-shaped utility). A general S-shaped utility function $U : \mathbb{R} \rightarrow \mathbb{R}$ with the reference point $B \in \mathbb{R}$ has the expression

$$U(x) = \begin{cases} U_1(x), & x \geq B, \\ U_2(x), & x < B, \end{cases} \quad (5)$$

and satisfies the following properties:

- (i) U is increasing on \mathbb{R} , $U = U_1$ is strictly concave on (B, ∞) , and $U = U_2$ is convex on $(-\infty, B)$.
- (ii) $U_1(B) = U_2(B)$ and $U'_1(B+) = U'_2(B-) = \infty$.
- (iii) Inada condition: $U'_1(\infty) = 0$.

The conjugate function $I : (0, \infty) \rightarrow \mathbb{R}$ is given by $I(y) = \arg \sup_{x \geq B} [U(x) - xy] = (U'_1)^{-1}(y)$. Note that in Definition 2, there is no requirement for a finite left endpoint of the domain of the utility function (known as the liquidation boundary). We solve the FSD problem (3) with a general S-shaped utility and hence illustrate that using the FSD constraint can replace the liquidation boundary for risk management.

Theorem 1. *With a general S-shaped utility in Definition 2, the optimal solution of Problem (3) is given by*

$$X_{FSD}^* = \begin{cases} (U'_1)^{-1}(\lambda\rho), \text{ if } \left\{ \rho < \frac{1}{\lambda} U'_1(Q_0(1 - F_\rho(\rho))) \text{ and } Q_0(1 - F_\rho(\rho)) \geq B \right\} \text{ or } \left\{ \rho \leq \frac{1}{\lambda} U'_1(C) \text{ and } Q_0(1 - F_\rho(\rho)) < B \right\}; \\ Q_0(1 - F_\rho(\rho)), \text{ if } \left\{ \rho \geq \frac{1}{\lambda} U'_1(Q_0(1 - F_\rho(\rho))) \text{ and } Q_0(1 - F_\rho(\rho)) \geq B \right\} \text{ or } \left\{ \rho > \frac{1}{\lambda} U'_1(C) \text{ and } Q_0(1 - F_\rho(\rho)) < B \right\}. \end{cases} \quad (6)$$

where (i) the Lagrange multiplier $\lambda > 0$ is solved from the binding budget constraint $\mathbb{E}[\rho X_{FSD}^*] = \bar{x}$, and (ii) for any $Q_0(1 - F_\rho(\rho)) < B$, the (state-dependent) tangent point $C \in (B, \infty)$ is solved from

$$\frac{U_1(C) - U_2(Q_0(1 - F_\rho(\rho)))}{C - Q_0(1 - F_\rho(\rho))} = U'_1(C). \quad (7)$$

Proof of Theorem 1. As the objective in Problem (3) is an increasing function of X , the optimal wealth X_{FSD}^* of Problem (3) is counter-comonotonic to the pricing kernel ρ (see, e.g., He and Zhou (2011)). Denote by ξ the uniform transformation of ρ such that ξ has the uniform distribution on $[0, 1]$ and $Q_\rho(\xi) = \rho$. Hence, the optimal wealth X_{FSD}^* under the first-order stochastic dominance constraint should satisfy

$$X_{FSD}^* \geq Q_0(1 - \xi), \quad Q \in \mathcal{Q}.$$

Hence, Problem (3) is translated to the following problem:

$$\max_{X \geq Q_0(1 - \xi), \mathbb{E}[\rho X] = x} \mathbb{E}[U(X)]. \quad (8)$$

Further, Problem (8) is converted to a state-dependent pointwise optimization problem:

$$\max_{X \geq Q_0(1-\xi)} \{U(X) - \lambda \rho X\}, \quad (9)$$

where $\lambda > 0$ is a to-be-determined Lagrange multiplier such that $\mathbb{E}[\rho X] = \bar{x}$. To solve Problem (9), we have the following two cases:

(i) for any $\omega \in \Omega$ satisfying $Q_0(1 - \xi(\omega)) < B$, we solve the tangent point $C(\omega)$ from (7) and have

$$X_{\text{FSD}}^* = \begin{cases} (U_1')^{-1}(\lambda \rho), & \text{if } (U_1')^{-1}(\lambda \rho) > C \text{ and } Q_0(1 - \xi) < B; \\ Q_0(1 - \xi), & \text{if } (U_1')^{-1}(\lambda \rho) \leq C \text{ and } Q_0(1 - \xi) < B. \end{cases}$$

(ii) for any $\omega \in \Omega$ satisfying $Q_0(1 - \xi(\omega)) \geq B$, we have

$$X_{\text{FSD}}^* = \begin{cases} (U_1')^{-1}(\lambda \rho), & \text{if } (U_1')^{-1}(\lambda \rho) > Q_0(1 - \xi) \text{ and } Q_0(1 - \xi) \geq B; \\ Q_0(1 - \xi), & \text{if } (U_1')^{-1}(\lambda \rho) \leq Q_0(1 - \xi) \text{ and } Q_0(1 - \xi) \geq B. \end{cases}$$

Further, as $\xi = F_\rho(\rho)$, we derive the optimal solution X_{FSD}^* given by (6). \square

In the literature, a liquidation boundary is needed for the optimization of the S-shaped utility, otherwise the problem has no solution (mathematically, it is because one cannot establish a concave envelope for the S-shaped utility without a lower bound in the domain). In the problem of FSD, we do not require the liquidation boundary for the S-shaped utility. The solution is twofold. In some good scenarios, it behaves like the classic solution. In some bad scenarios, it behaves like the benchmark quantile. From the solution, we can see that the FSD constraint acts as a good substitute of the liquidation boundary.

4 SSD Problem

4.1 SSD Problem under Non-concavity: Analytical Difficulty

Let us restate the results of Wang and Xia (2021) on strictly concave utilities.

Theorem 2 (Theorem 5.10 of Wang and Xia (2021)). *Let $\bar{x} > x_0$. For a strictly concave utility U with appropriate regularity conditions, the optimal solution to Problem (4) is $X_{\text{SSD}}^* = Q_{\text{SSD}}^*(1 - F_\rho(\rho))$ with*

$$Q_{\text{SSD}}^*(s) = I(\lambda(Q_\rho(1 - s) - y_{\text{SSD}}^*(1 - s))), \quad s \in (0, 1), \quad (10)$$

where $y_{SSD}^* : [0, 1] \rightarrow [0, \infty)$ is a function given by the system

$$\begin{cases} y_{SSD}^* \text{ is right-continuous and } 0 \leq \frac{dy_{SSD}^*(t)}{dQ_\rho(t)} \leq 1, \quad Q_\rho(t) - y_{SSD}^*(t) > 0 \text{ for all } t \in (0, 1); \\ z_{SSD}^*(s) \triangleq - \int_s^1 (I(\lambda(Q_\rho(t) - y_{SSD}^*(t))) - Q_0(1-t)) dt, \quad s \in [0, 1]; \\ \frac{dy_{SSD}^*(t)}{dQ_\rho(t)} \begin{cases} \in [0, 1], & z_{SSD}^*(t) = 0; \\ = 0, & z_{SSD}^*(t) < 0, \end{cases} \quad dQ_\rho\text{-a.e.}, \end{cases} \quad (11)$$

and the Lagrange multiplier $\lambda > 0$ is determined by the binding budget constraint equation

$$\int_0^1 Q_{SSD}^*(s) Q_\rho(1-s) ds = \bar{x}. \quad (12)$$

In the proof of Wang and Xia (2021), the procedure of solving Problem (4) starts with a view of quantile formulation (He and Zhou (2011); Xia and Zhou (2016); Xu (2016)). Specifically, we define

$$\begin{aligned} \mathcal{W} &\triangleq \{w : [0, 1] \rightarrow [0, \infty) | w(0) = 0, w \text{ is increasing and concave}\}, \\ \mathcal{W}_1 &\triangleq \{w \in \mathcal{W} | w(1) = 1\}. \end{aligned}$$

Define

$$\begin{aligned} \mathcal{Q}_2(Q_0) &\triangleq \left\{ Q \in \mathcal{Q} \mid \int_{[0,1]} Q(s) dw(s) \geq \int_{[0,1]} Q_0(s) dw(s) \text{ for all } w \in \mathcal{W} \right\} \\ &= \left\{ Q \in \mathcal{Q} \mid \int_{[0,1]} Q(s) dw(s) \geq \int_{[0,1]} Q_0(s) dw(s) \text{ for all } w \in \mathcal{W}_1 \right\}. \end{aligned} \quad (13)$$

In view of quantile formulation approach, we are going to change the optimization among the random variable X to its quantile function Q_X . We can hence express the objective in SSD Problem (4) as $\mathbb{E}[U(X)] = \int_0^1 U(Q_X(s)) ds$. Based on the counter-monotonic dependence between the optimal solution X and the pricing kernel ρ (see He and Zhou (2011) and the proof of Theorem 1), we can express the budget constraint as $\mathbb{E}[\rho X] = \int_0^1 Q_X(s) Q_\rho(1-s) ds$. According to Föllmer and Schied (2016), SSD Problem (4) reads as an optimal quantile problem

$$\max_{Q \in \mathcal{Q}_2(Q_0)} \int_0^1 U(Q(s)) ds \quad \text{s.t.} \quad \int_0^1 Q(s) Q_\rho(1-s) ds \leq \bar{x}. \quad (14)$$

The next step of solving Problem (4) is a conversion from Problem (14) to

$$\max_{Q \in \mathcal{Q}} \int_0^1 U(Q(s)) ds \quad \text{s.t.} \quad \begin{cases} \int_0^1 Q(s) Q_\rho(1-s) ds \leq x, \\ \inf_{w \in \mathcal{W}_1} \left(\int_{[0,1]} (Q(s) - Q_0(s)) dw(s) \right) \geq 0. \end{cases} \quad (15)$$

If the optimal solution of the original problem satisfies the second constraint in Problem (15), then the

optimal solution of Problem (15) is the same as that of the original problem and it is considered as a trivial case. In the non-trivial case, for any $\lambda > 0$, $Q \in \mathcal{Q}$ and $w \in \mathcal{W}$, we let

$$K(Q, w; \lambda) = \int_0^1 U(Q(s))ds - \lambda \int_0^1 Q(s)Q_\rho(1-s)ds + \int_{[0,1]} (Q(s) - Q_0(s))dw(s).$$

One needs to consider the following max-min problem for K :

$$\max_{Q \in \mathcal{Q}} \min_{w \in \mathcal{W}} K(Q, w; \lambda). \quad (16)$$

Unfortunately, the solution procedure of the SSD Problem under non-concave utility is stuck at this step, because the desired Sion's max-min theorem requires that K is concave in Q , which does not hold generally. In an alternative clue of concavifying U (see Liang and Liu (2020)), one cannot guarantee that the concavification principle is valid (i.e., the optimal wealth variable under the concave envelope is almost surely not located in the region where the original utility and its concave envelope do not coincide). Even if a similar form of Theorem 2 is established for general non-concave utilities, one needs to solve the optimal pair (y^*, z^*) from the system (11), which is an infinite-dimensional optimization problem over the functional space. Wang and Xia (2021) propose some explicit optimal solutions based on specific and technical assumptions on U , Q_ρ and Q_0 . Beyond these, there is no general analytical expression for optimal solutions.

Nevertheless, Theorem 5.10 of Wang and Xia (2021) provides an important idea that the optimal solution may be characterized by the optimal pair (y^*, z^*) from the system (11), and hence we can obtain some heuristics to construct suboptimal solutions based on numerical algorithms and even neural networks. Specifically, we define a concept of the **poor performance region**:

$$C \triangleq \{t \in (0, 1) | I(\lambda Q_\rho(t)) - Q_0(1-t) < 0\}.$$

Here for the non-concave utility U , we define $I(y) \triangleq \inf\{\arg \sup_{x \in \mathbb{R}} [U(x) - xy]\}$, $y > 0$ whenever applicable. For example, if U is a S-shaped utility with the domain $[L, \infty)$ where $L \in \mathbb{R}$, we have $I(\cdot)$ is well-defined, while if the domain is \mathbb{R} , we have $I(\cdot) \equiv -\infty$.

Remark: "Whenever applicable" means that the function I is finite for any $y \in (0, \infty)$. That is, the utility U has a finite concave envelope function (the smallest concave function dominating U ; see Liang and Liu (2020)). In this case, $I(\cdot)$ is right-continuous and decreasing on $(0, +\infty)$.

In the set C , we compare the unconstrained classic solution $I(\lambda Q_\rho(t))$ with the SSD benchmark $Q_0(1-t)$. If $C = \emptyset$, then it means that the unconstrained solution automatically satisfies the SSD constraint and Q_{SSD}^* should be the same as the unconstrained solution. Next, we discuss the non-trivial case (i.e., $C \neq \emptyset$). For the scenario t on this region, the unconstrained solution $I(\lambda Q_\rho(t))$ is smaller (i.e., performing worse) than the SSD benchmark $Q_0(1-t)$. From Definition 1, the SSD constraint $Q_{\text{SSD}}^* \succeq_{(2)} Q_0$ reads as

$$\int_0^s Q_{\text{SSD}}^*(t)dt \geq \int_0^s Q_0(t)dt \quad \text{for any } s \in (0, 1),$$

which is reflected in the system (11):

$$z_{\text{SSD}}^*(s) = - \int_s^1 (Q_{\text{SSD}}^*(1-t) - Q_0(1-t)) dt \leq 0 \quad \text{for any } s \in (0, 1).$$

which translates to

$$z_{\text{SSD}}^*(s) = - \int_s^1 (I(\lambda(Q_\rho(t) - y_{\text{SSD}}^*(t))) - Q_0(1-t)) dt \leq 0 \quad \text{for any } s \in (0, 1). \quad (17)$$

The theorem inspires that some correction function y_{SSD}^* should be added to satisfy the constraint (17). In the next subsection, we provide a numerical algorithm and design the correction function to obtain a sub-optimal solution.

4.2 SSD Problem: Numerical Algorithm

Inspired by the structure of the optimal solution (10), We proceed to present a numerical algorithm to propose a suboptimal solution Q_{sub} , where we design a correction function y_{sub} based on the value of z_{sub} in different sections of the poor performance region C .

Detecting the structure of the poor performance region is the key task. We first define a function

$$y_0(s) \triangleq \inf\{y \geq 0 | I(\lambda(Q_\rho(s) - y)) - Q_0(1-s) \geq 0\}, \quad s \in (0, 1). \quad (26)$$

Hence, we alternatively write the poor performance region as

$$C = \{t \in (0, 1) | y_0(t) > 0\}. \quad (27)$$

For some very poorly-performed scenarios $t \in C$, the function y_0 is adopted such that $Q_{\text{sub}}(1-t) = I(\lambda(Q_\rho(t) - y_0(t))) = Q_0(1-t)$.

The general idea in the construction of the sub-optimal solution to SSD Problem (4) is: When $z_{\text{sub}} \leq 0$, we use the classic solution to achieve optimality (now $y_{\text{sub}} = 0$ or constant, and Q_{SSD} is the form of I); When $z_{\text{sub}} > 0$, we set $y_{\text{sub}} = y_0$ such that $Q_{\text{sub}} = Q_0$ to satisfy the SSD constraint. Throughout the algorithm design, we need to guarantee that y_{sub} is increasing and non-negative.

We therefore propose Algorithm 1 below, named the *Poor-Performance-Region Algorithm*. Based on Theorem 2, we design a closed-form sub-optimal solution to Problem (14):

$$Q_{\text{sub}}(s) = \sum_{i=0}^n I(\lambda_{\text{sub}}(Q_\rho(1-s) - y_0(t_i))) \mathbb{1}_{\{s \in (1-a_{i+1}, 1-t_i)\}} + \sum_{i=1}^n Q_0(s) \mathbb{1}_{\{s \in [1-t_i, 1-a_i]\}}, \quad s \in (0, 1). \quad (28)$$

This quantile function is also given in Eq. (24). The key idea is to use an increasing step function $y_{\text{SSD}}^*(\cdot)$ for approximation. The financial insight is that the decision maker should follow the SSD benchmark quantile Q_0 on some poor performance scenario and conduct the unconstrained optimal strategy

Algorithm 1 Poor-Performance-Region Algorithm for SSD Problem (4) with general utilities

- 1: We solve the classic problem without the SSD constraint and obtain the optimal quantile Q_{cla} . The Lagrange multiplier is denoted by $\lambda_{\text{cla}} \in (0, \infty)$, which is solved from the following equation

$$\bar{x} = \int_0^1 Q_\rho(s) I(\lambda_{\text{cla}} Q_\rho(s)) ds.$$

If

$$- \int_t^1 (I(\lambda_{\text{cla}} Q_\rho(s)) - Q_0(1-s)) ds \leq 0$$

holds for any $t \in [0, 1]$, then the optimal solution is $Q_{\text{cla}}(\cdot) \triangleq I(\lambda_{\text{cla}} Q_\rho(1 - \cdot))$. Otherwise, we start the procedure below.

- 2: The Lagrange multiplier is initially set as the above λ (to be determined at last). Compute the set

$$C = \{t \in (0, 1) | I(\lambda Q_\rho(t)) - Q_0(1-t) < 0\}.$$

- 3: If $C = \emptyset$, then the optimal solution is Q_{cla} . Otherwise, specify an appropriate $n \in \mathbb{N}$ and write $C = \cup_{i=1}^n (a_i, b_i)$ with $a_i < b_i$. Further we set $a_{n+1} = 1$.
- 4: For $i = n, (n-1), \dots, 1$ (Steps 4-6), we compute

$$y_0(s) = \inf\{y \geq 0 | I(\lambda(Q_\rho(s) - y)) - Q_0(1-s) \geq 0\}, \quad s \in (a_i, b_i). \quad (18)$$

Define

$$g_i(s) = - \int_s^{a_{i+1}} (I(\lambda(Q_\rho(t) - y_0(s))) - Q_0(1-t)) dt, \quad s \in (a_i, b_i). \quad (19)$$

- 5: We compute

$$t_i = \sup \left\{ t \in [a_i, b_i] \mid g_i(t) + z_{\text{sub}}(a_{i+1}) \mathbb{1}_{\{i \neq n\}} > 0 \right\}, \quad (20)$$

where $z_{\text{sub}}(\cdot)$ will be determined in Step 6. If $\{t \in [a_i, b_i] | g_i(t) + z_{\text{sub}}(a_{i+1}) \mathbb{1}_{\{i \neq n\}} > 0\} = \emptyset$, set $t_i = a_i$.

- 6: Set

$$y_{\text{sub}}(\cdot) \equiv y_0(t_i) \text{ on } (t_i, a_{i+1}) \quad \text{and} \quad y_{\text{sub}}(\cdot) = y_0(\cdot) \text{ on } (a_i, t_i). \quad (21)$$

Define $z_{\text{sub}}(\cdot)$ as follows:

$$z_{\text{sub}}(s) \triangleq - \int_s^1 (I(\lambda(Q_\rho(t) - y_{\text{sub}}(t))) - Q_0(1-t)) dt, \quad s \in [a_i, a_{i+1}]. \quad (22)$$

- 7: Set $t_0 = 0$ and $y_0(t_0) = 0$. After the iteration, we have Eq. (21) for $i = n, \dots, 1$ and $y_{\text{sub}}(\cdot) \equiv y_0(t_0)$ on $(t_0, a_1]$. We then verify whether $y_{\text{sub}}(\cdot)$ satisfies the monotonicity condition (non-decreasing over $(0, 1)$). If the condition holds, proceed to Step 14; otherwise, apply the correction procedure and proceed to Step 8.
- 8: For $i = n, (n-1), \dots, 2$ (Steps 8-12), check whether $y_0(\cdot)$ is increasing (non-decreasing) over (a_{i-1}, a_{i+1}) . If yes, skip and proceed to next iteration; if not, proceed to Step 11.
- 9: Compute $y_0(\cdot)$ over (a_{i-1}, b_{i-1}) and (a_i, b_i) by Eq. (18).
- 10: Redefine

$$g_i(s) = - \int_s^{\bar{s}} (I(\lambda(Q_\rho(t) - y_0(s))) - Q_0(1-t)) dt, \quad s \in (a_{i-1}, b_{i-1}),$$

where $\bar{s} = \inf\{t \geq a_i | y_0(t) - y_0(s) \geq 0\}, t \in [a_i, b_i]$.

- 11: Compute

$$t_{\text{left}} = \sup\{t \in [a_1, b_1] | g_1(t) > 0\}, \quad t_{\text{right}} = \bar{s}. \quad (23)$$

12: Replace the initial $y_{\text{sub}}(\cdot)$ over $(t_{\text{left}}, t_{\text{right}})$ and set

$$y_{\text{sub}}(\cdot) \equiv y_0(t_{\text{left}}) \text{ on } (t_{\text{left}}, t_{\text{right}}).$$

13: After the iteration, check whether $y_{\text{sub}}(\cdot)$ satisfy the monotonicity condition. If yes, proceed to next step; otherwise, the algorithm may fail.

14: Hence, we design the sub-optimal solution by

$$Q_{\text{sub}}(s) = \begin{cases} I(\lambda(Q_\rho(1-s) - y_0(t_n))), & s \in (1 - a_{n+1}, 1 - t_n]; \\ I(\lambda(Q_\rho(1-s) - y_0(1-s))) \equiv Q_0(s), & s \in (1 - t_n, 1 - a_n]; \\ \dots & \\ I(\lambda(Q_\rho(1-s) - y_0(t_0))), & s \in (1 - a_1, 1 - t_0). \end{cases} \quad (24)$$

15: Set

$$z_i^*(t) = - \int_t^1 (I(\lambda(Q_\rho(s) - y_0(t_i))) - Q_0(1-s)) ds, \quad t \in (\max\{a_i, t_i\}, a_{i+1}).$$

If for any $i = 1, \dots, n$, $z_i^*(\cdot) \leq 0$ always holds on the interval $(\max\{a_i, t_i\}, a_{i+1})$, this Q_{sub} is sub-optimal.

16: Using a bisection method, we determine $\lambda_{\text{sub}} \in (0, \infty)$ from the following equation

$$\bar{x} = \int_0^1 Q_\rho(s) Q_{\text{sub}}(1-s) ds. \quad (25)$$

$I(\lambda_{\text{sub}}(Q_\rho(1-s) - y_0(t_i)))$ otherwise.

Here are some explanations of the algorithm design.

- a. In this algorithm, the partition points $\{a_i\}_{i=1}^n$ and $\{t_i\}_{i=1}^n$ of the poor performance region play an essential role in determining the structure of the optimal solution.
- b. In Step 2: In the whole procedure, we are solving out the structure of the optimal solution and the Lagrange multiplier. For the latter, note that the initial Lagrange multiplier may not satisfy the budget constraint. But it is a good initial point to start the algorithm. It will be determined in the last step.
- c. In Step 3: Because $I(\lambda Q_\rho(\cdot))$ and $Q_0(1-\cdot)$ are both nonincreasing, the set C can be written as the union of disjoint intervals $\cup_{i=1}^n (a_i, b_i)$ or $\cup_{i=1}^\infty (a_i, b_i)$. In the latter case, to construct a numerically tractable solution, we use the union of the first n disjoint intervals, where n can be specified based on one's computational capability.
- d. In Steps 4-5: For any $t \in [b_i, a_{i+1})$, we have

$$I(\lambda^*(Q_\rho(s) - y_0(t))) - Q_0(1-s) \geq I(\lambda^*(Q_\rho(s))) - Q_0(1-s) \geq 0, \quad s \in (t, a_{i+1}].$$

We then compute

$$g_i(t) = - \int_t^{a_{i+1}} (I(\lambda^*(Q_\rho(s) - y_0(t))) - Q_0(1-s)) ds \leq 0.$$

Hence, any $t \in [b_i, a_{i+1})$ satisfies the SSD constraint. We desire to search the first point t_i on (a_i, b_1) which does not satisfy the constraint.

- e. In Steps 8-12, we need to check whether the constructed $y_{\text{sub}}(\cdot)$ is non-decreasing on $(0,1)$ to make the solution valid. It holds in many cases. However, in some extreme cases, we could still ensure the monotonicity by redesigning the construction of t_i defined in Eq. (20), which is named t_{left} in Eq. (23). The specific case will be shown in Section 5.
- f. In Step 14, in many cases, one can design that $Q_{\text{sub}}(\cdot) = I(\lambda(Q_\rho(1-\cdot) - y_0(\cdot))) = Q_0(\cdot)$ on $(1-t_n, 1-a_n]$.
- g. In Step 15, we need to check the condition holds numerically. It holds in many cases.

In the later sections, based on Algorithm 1, we are able to provide the numerical illustration for the SSD Problem (4) with various concrete settings.

5 Numerical Results

Our study is motivated by the Black-Scholes model in a complete market. A classic Black-Scholes model consists of one riskless bond ($\frac{dB_t}{B_t} = rdt$, $t \in [0, T]$, where the risk-free rate is $r = 0.05$) and one stock ($\frac{dS_t}{S_t} = \mu_S dt + \sigma_S dW_t$, $t \in [0, T]$, which is a geometric Brownian motion with the expected return rate $\mu_S = 0.086$ and the volatility parameter $\sigma_S = 0.3$ and $\{W_t\}_{0 \leq t \leq T}$ is a standard Brownian motion). The wealth process is given by $dX_t = (rX_t + (\mu_S - r)\pi_t)dt + \sigma_S \pi_t dW_t$, $t \in [0, T]$ and $X_0 = \bar{x}$, where $\{\pi_t\}_{0 \leq t < T}$ is the control process representing the investment amount in the stock and $T \in (0, \infty)$ is the evaluation time of investment. We define the pricing kernel process $\{\rho_t\}_{0 \leq t \leq T}$ by

$$\frac{d\rho_t}{\rho_t} = -r dt - \theta dW_t, \quad t \in [0, T], \quad (29)$$

where we denote the market price of risk by $\theta \triangleq (\mu_S - r)/\sigma_S$.

As the market is complete and one can use the martingale method to duplicate the optimal portfolio process, it is sufficient to solve the optimal terminal wealth variable via the static problem (1) (see, e.g., Liang and Liu (2024)). Hence, our focus is solving the optimal wealth variable in Problem (1). Adapting to Problem (1), we denote the terminal variables of pricing kernel and wealth by $\rho := \rho_T$ and $X := X_T$, with a slight abuse of notation. Solving from Eq. (29), ρ follows the log-normal distribution (i.e., $\log(\rho) \sim N(-(r + \theta^2/2)T, (\theta\sqrt{T})^2)$) and has a quantile function

$$Q_\rho(t) = \exp\left\{\theta\sqrt{T}\Phi^{-1}(t) - (r + \theta^2/2)T\right\} \triangleq \exp\left\{\sigma\Phi^{-1}(t) + \mu\right\}, \quad t \in (0, 1), \quad (30)$$

where we denote by Φ^{-1} the standard normal quantile function and define $\sigma \triangleq \theta\sqrt{T}$ and $\mu \triangleq -(r + \theta^2/2)T$. In Sections 5-6, we will mainly consider this Q_ρ in Eq. (30) and specify different benchmark quantile functions Q_0 and various utility functions.

We specify the parameters: the risk-free rate is $r = 0.05$; the expected return rate $\mu_S = 0.086$; the volatility parameter $\sigma_S = 0.3$; The evaluation time of investment is $T = 20$ (years). It follows that the

market price of risk is $\theta = (\mu - r)/\sigma = 0.12$. We compute that $\sigma = 0.5367$ and $\mu = -1.1440$. We numerically illustrate our result by using the Black-Scholes model above.

5.1 FSD Problem: S-shaped Utility (Theorem 1)

We begin by specifying a S-shaped utility $U : [L, \infty) \rightarrow \mathbb{R}$, following the general S-shaped utility formulation in Definition 2:

$$U(x) = \begin{cases} \frac{x^p}{p}, & x \geq 0, \\ -k(-x)^q, & L \leq x < 0, \end{cases} \quad (31)$$

where the parameters are set to $p = 0.6$, $q = 0.5$, and $k = 2$.

We then consider two portfolio selection problems. The first is Problem (3) with the general setting of S-shaped utility in Definition 2 (In particular, Eq. (31)) and the benchmark quantile $Q_0(t) = 10t^2 - 1$, $t \in [0, 1]$. The second is the Merton problem (1) using the S-shaped utility setting in Eq. (31):

$$\max_{X \in L^0} \mathbb{E}[U(X)], \text{ s.t. } \mathbb{E}[\rho X] \leq \bar{x}, X \geq L \text{ a.s.}, \quad (32)$$

where the liquidation boundary is given by $L = -5$. Here we add the liquidation boundary in order to make the second problem well defined and compare with the first problem.

In this example, the first-order SD constraint acts a similar role as the liquidation constraint: if $Q_0(1 - F_\rho(\rho)) = Q_0(0)$, then the optimal solution X^* locates at the boundary $Q_0(1 - F_\rho(\rho))$, otherwise X^* is the same as the classic solution $(U'_1)^{-1}(\lambda\rho)$.

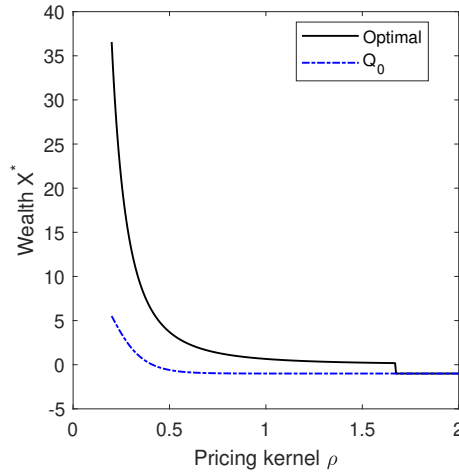

Figure 1: First-order SD constraint: $\bar{x} = 5$

5.2 SSD Problem: Power Utility

We first assume the decision maker has a CRRA utility

$$U(x) = \frac{1}{p}x^p, \quad x > 0, \quad (33)$$

where $p = 0.6$. We suppose that the benchmark quantile Q_0 also follows the log-normal distribution:

$$Q_0(t) = \exp \{ \sigma_0 \Phi^{-1}(t) + \mu_0 \}, \quad t \in [0, 1].$$

The settings are given in Table 1.

r	μ_S	σ_S	θ	T	μ	σ	\bar{x}	p
0.05	0.086	0.3	0.12	20	-1.1440	0.5367	10	0.6

Table 1: Parameter setting in the numerical illustration.

For the concave utility specified in Eq. (33), the applicability of Proposition 6.8 in Wang and Xia (2021) to power utility with a log-normal pricing kernel provides a theoretical benchmark. Our algorithm's result coincides with the characterization in Wang and Xia (2021). Consequently, the algorithm attains the optimal solution in the following cases in Figure 2. For comparison, we also compute the classical optimal solution obtained without the SSD constraint and plot the figure.

	parametrization	budget of Q_0	poor performance region C	λ	λ_{cla}	partition parameter
(a)	$(\mu_0, \sigma_0) = (3, 1)$	7.1231	(0.6092, 1)	0.9104	0.9003	$t_1 = 1$
(b)	$(\mu_0, \sigma_0) = (3, 0.6)$	6.4109	(0.4978, 1)	0.9471	0.9003	$t_1 = 1$
(c)	$(\mu_0, \sigma_0) = (3, 1.4)$	9.2876	(0, 0.0179)	0.9003	0.9003	$t_1 = 0$
(d)	$(\mu_0, \sigma_0) = (3.2, 1)$	8.7002	(0.2858, 1)	0.9430	0.9003	$t_1 = 1$
(e)	$(\mu_0, \sigma_0) = (2.3, 2)$	9.2691	(0, 0.4309)	1.1951	0.9003	$t_1 = 0.0057$
(f)	$(\mu_0, \sigma_0) = (1.5, 2.5)$	9.8096	(0, 0.6248)	1.9965	0.9003	$t_1 = 0.0654$

Table 2: Numerical results in Figure 2.

The basic logic is that:

- (i) If the value of the pricing kernel is small, then the optimal wealth value is larger. Hence, the pricing kernel value is a signal of the market state: A small value shows a good market scenario.
- (ii) If the poor performance region C is smaller, then the optimal wealth is better (compared to the SSD constraint). This is because the SSD constraint is easier to achieve and the optimal wealth is closer to the classic unconstrained solution X_{cla} .

We apply the Poor-Performance-Region Algorithm (PPRA), the explanations and financial insights from Figure 2 and Table 2 are as follows:

1. Figure 2 (a) vs (b) vs (d): When the market performs poorly, the optimal wealth must coincide with

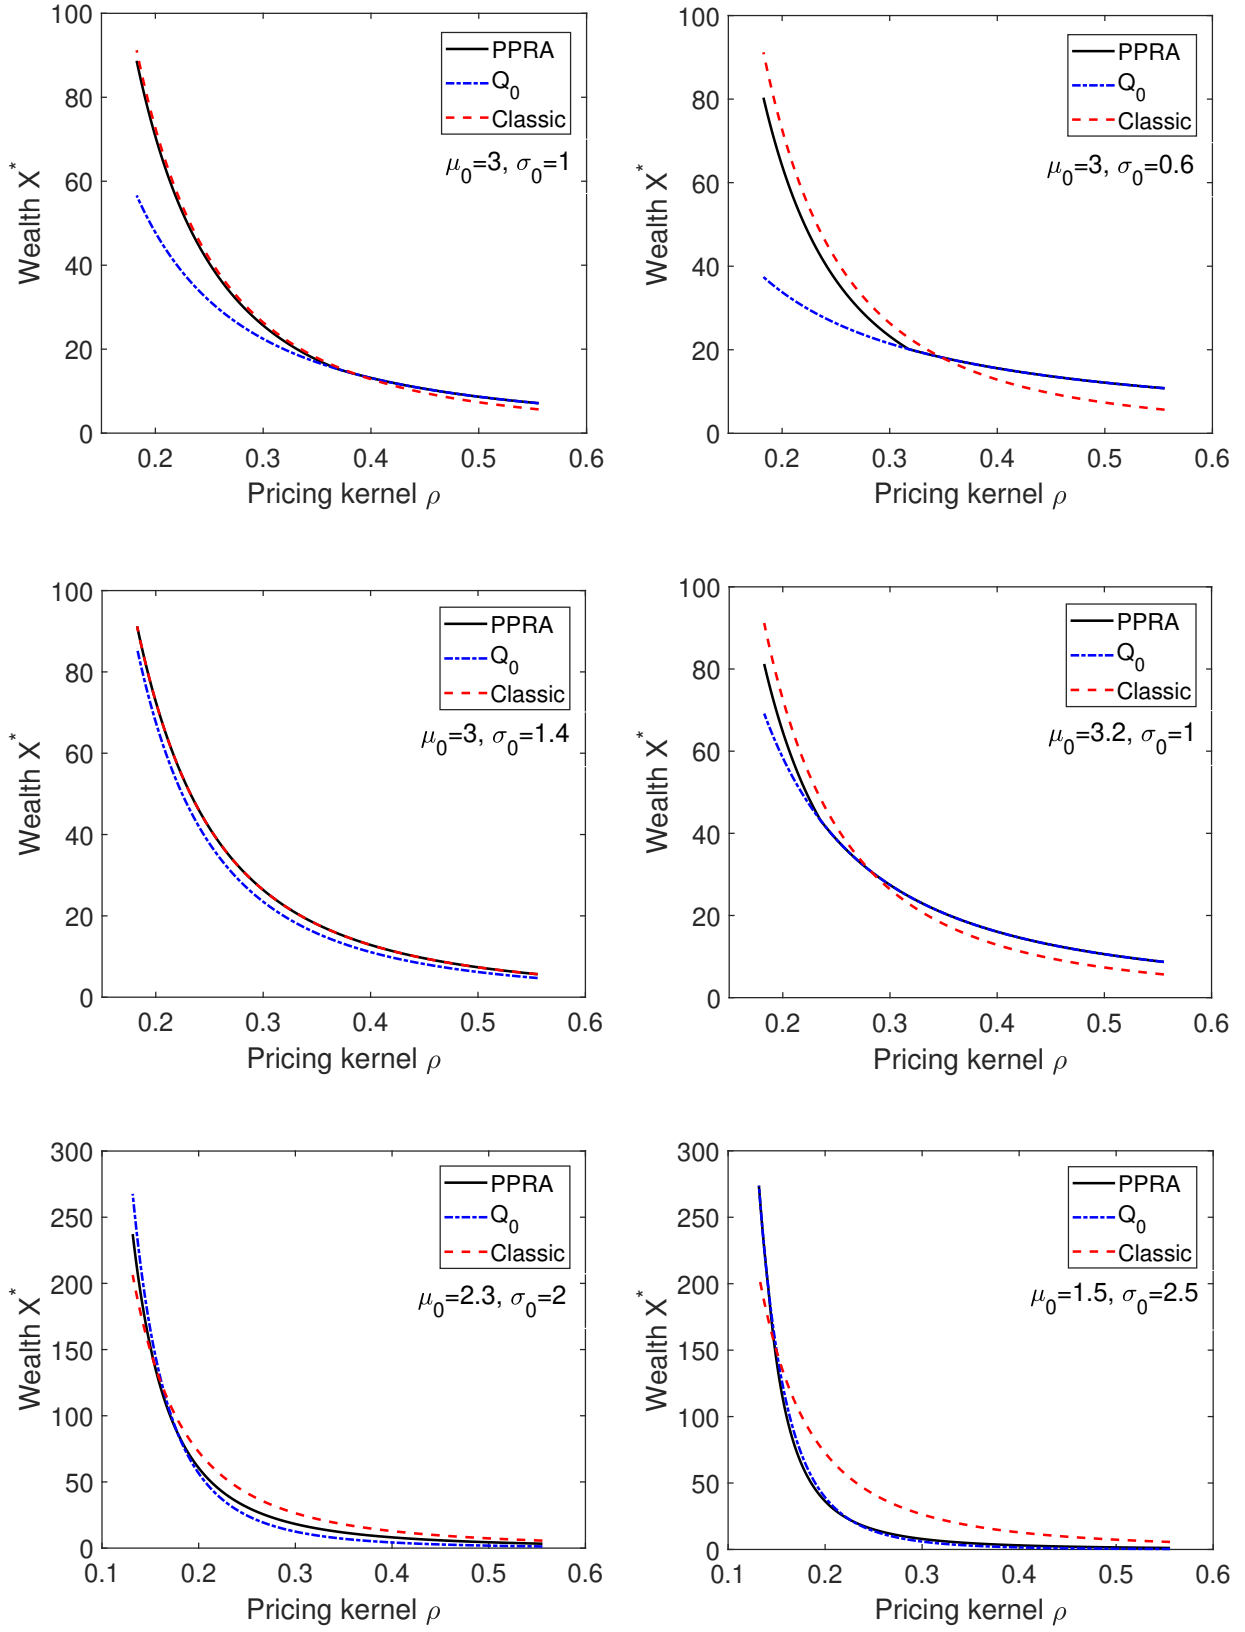

Figure 2: Impacts of μ_0 and σ_0 .

the benchmark. This is because, in such adverse scenario, the benchmark provides a large value, and the SSD constraint serves to guarantee a minimum safety level and reduce risk.

2. Figure 2 (c): The poor performance region is very small, which implies the classical solution inherently satisfies the SSD constraint. As a result, we observe that $\lambda = \lambda_{\text{cla}}$ and the optimal solution essentially coincides with the classical solution. This indicates that the benchmark plays only a limited role in shaping the optimal wealth.
3. Figure 2 (e) vs (f): The budget of Q_0 is close to \bar{x} , to ensure the SSD constraint, the optimal wealth would behave similarly to the benchmark. However, due to a different λ and a correction function $y_{\text{sub}}(\cdot)$ in the SSD problem, the solution between the SSD problem and the classical problem differs.

5.3 SSD Problem: S-shaped Utility

We use Algorithm 1 to study the sub-optimal solution of the SSD problem with S-shaped utility. First, we adopt the S-shaped utility setting in Eq. (31). We then suppose that the benchmark quantile Q_0 also follows a log-normal distribution:

$$Q_0(t) = \exp \{ \sigma_0 \Phi^{-1}(t) + \mu_0 \}, \quad t \in [0, 1].$$

We also compute the classic optimal solution without the SSD constraint. The settings are provided in Table 3.

r	μ_S	σ_S	θ	T	μ	σ	\bar{x}	p	k
0.05	0.086	0.3	0.12	20	-1.1440	0.5367	10	0.6	2

Table 3: Parameter setting in Figure 3.

	parametrization	budget of Q_0	poor performance region C	λ	λ_{cla}	partition parameter
(a)	$(\mu_0, \sigma_0) = (3, 1)$	7.1231	$(0.6089, 1)$	0.9105	0.8979	$t_1 = 1$
(b)	$(\mu_0, \sigma_0) = (3, 0.6)$	6.4109	$(0.4978, 1)$	0.9471	0.8979	$t_1 = 1$
(c)	$(\mu_0, \sigma_0) = (3, 0.8)$	6.6238	$(0.5394, 1)$	0.9255	0.8979	$t_1 = 1$
(d)	$(\mu_0, \sigma_0) = (3.2, 1)$	8.7002	$(0.2858, 1)$	0.9430	0.8979	$t_1 = 1$
(e)	$(\mu_0, \sigma_0) = (2.3, 2)$	9.2691	$(0, 0.4355) \cup (0.9669, 1)$	1.1987	0.8979	$t_2 = 1, t_1 = 0.0061$
(f)	$(\mu_0, \sigma_0) = (1.5, 2.5)$	9.8087	$(0, 0.6840) \cup (0.7726, 1)$	2.1508	0.8979	$t_2 = 1, t_1 = 0.0957$

Table 4: Numerical results in Figure 3.

We apply the Poor-Performance-Region Algorithm (PPRA), the explanations and financial insights from Figure 3 and Table 4 are summarized as follows:

1. Figure 3 (a) vs (b) vs (c) vs (d): These cases correspond to scenarios in which the poor performance region consists of a single interval. Numerically, a smaller μ_0 reduces the size of the poor performance region C whereas a smaller σ_0 enlarges it.

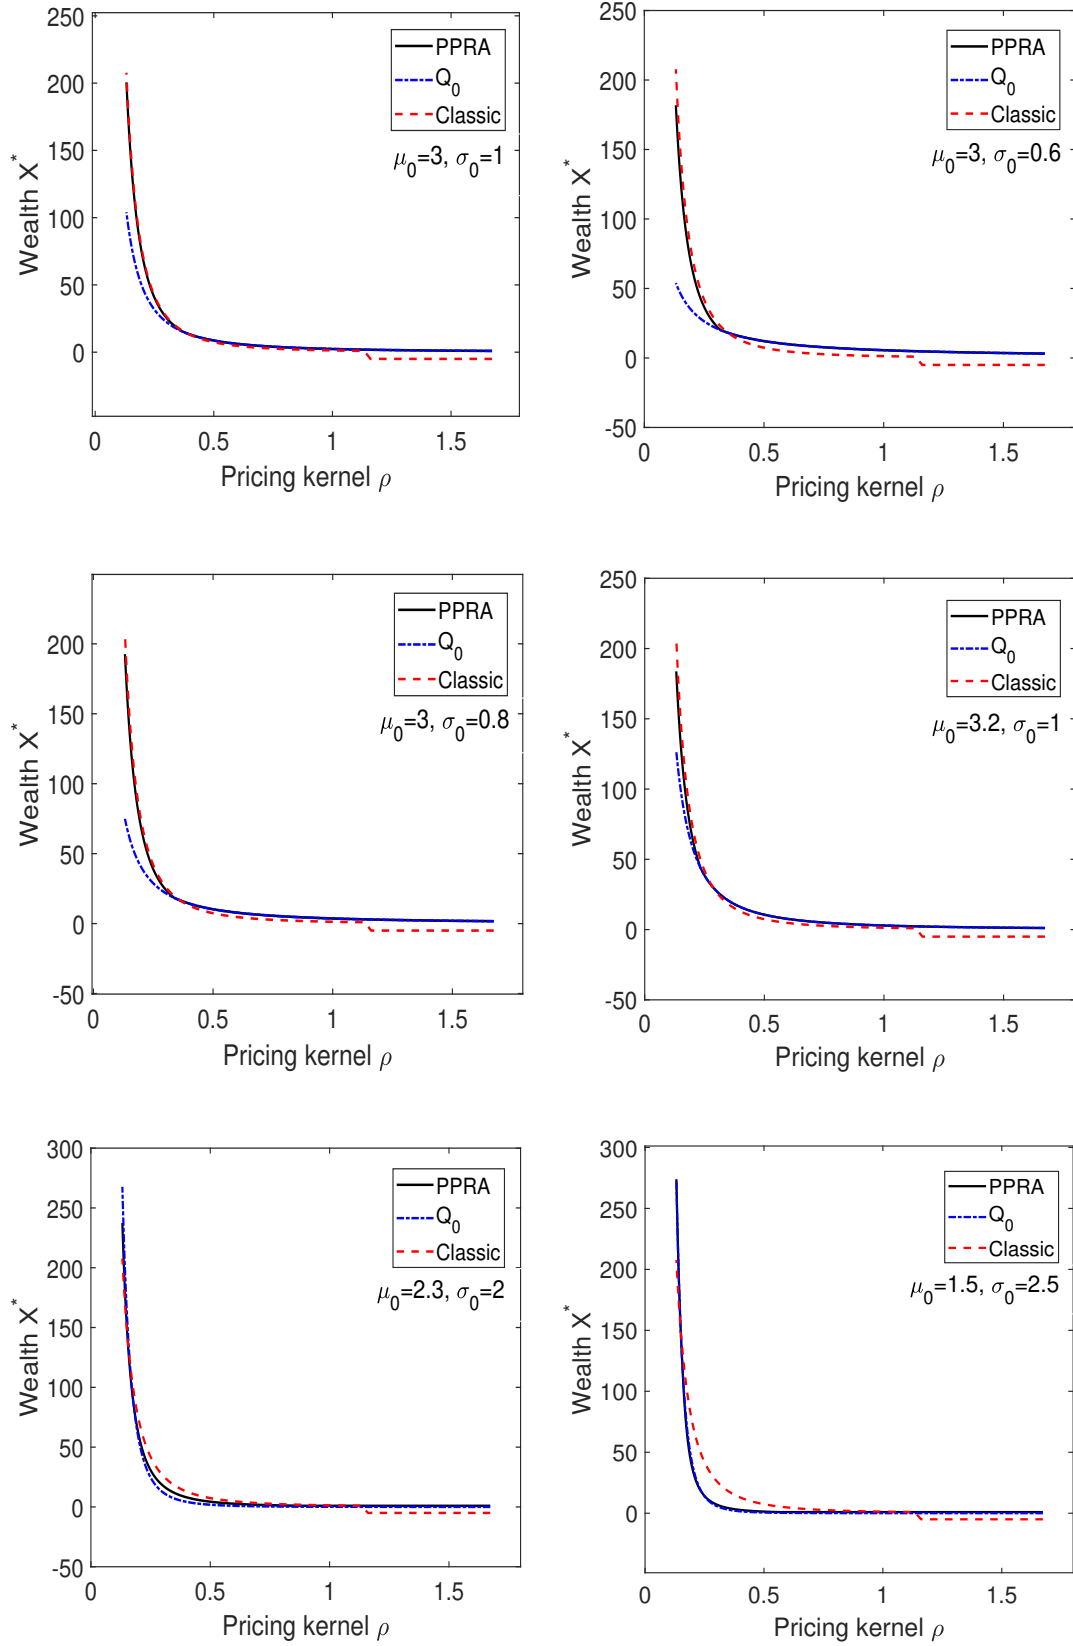

Figure 3: Impacts of μ_0 and σ_0 .

2. Figure 3: Across the S-shaped utility cases, we observe that when the market performs poorly, relative to the classical solution, the PPRA wealth exhibits a clear improvement, driven by the SSD constraint. Therefore, in adverse market scenario, the SSD constraint effectively performs as a risk-control mechanism, ensuring that the PPRA wealth remains at least as high as the benchmark wealth.
3. Figure 3 (e) vs (f): In these examples, the poor performance region splits into two disjoint intervals. We further observe that when the budget of Q_0 is close to the bound \bar{x} , the PPRA wealth becomes increasingly close to the benchmark. This phenomenon arises because a high level of the budget of Q_0 make the SSD constraint dominate the optimization.
4. Figure 3 (a) vs (b) vs (d): A deeper examination of the impact of the budget of Q_0 shows a consistent pattern: as the budget of Q_0 approaches the bar \bar{x} , the PPRA wealth converges towards the benchmark. This illustrates how the budget level critically shapes the structure of the PPRA wealth.

5.4 SSD Problem: Various Utilities and Benchmark Quantiles

Based on the proposed algorithm, we further extend its applicability to a broader class of the SSD problem. To assess the generality of our approach, we conduct numerical experiments using different utilities and benchmark quantiles Q_0 .

For the utility function $U(x)$, we consider several representative forms capturing different risk preference, as shown in Table 5.

	exponential	log	piecewise
$U(\cdot)$	$-\frac{1}{p} \exp(-p \cdot x), x > 0$	$\log(x), x > 0$	$\begin{cases} (x-1)^{p_1}, & x \geq 2 \\ -\lambda_1(1-x)^{q_1}, & 1 \leq x < 2 \\ x^{p_2} + C, & 0 \leq x < 1 \\ C - \lambda_2(-x)^{q_2}, & -1 \leq x < 0 \end{cases}$

Table 5: Setting of various utilities.

For the benchmark quantile Q_0 , we consider the following four cases, as shown in Table 6.

	exponential	log-normal	normal	uniform
$Q_0(\cdot)$	$-\frac{\log(1-t)}{\alpha} + k_0$	$\exp(\sigma_0 \cdot \Phi^{-1}(t) + \mu_0) + k_0$	$\sigma_0 \cdot \Phi^{-1}(t) + \mu_0$	$kt + k_0$

Table 6: Benchmark quantiles $Q_0(t)$, $t \in (0, 1)$.

The general settings coincide with the previous numerical examples and are given in Table 7.

r	μ_S	σ_S	θ	T	μ	σ
0.05	0.086	0.3	0.12	20	-1.1440	0.5367

Table 7: General setting in Figures 4-5.

We investigate several combinations of the utilities and the benchmark quantiles. To illustrate the effectiveness of our proposed algorithm, we present the most representative cases under the parameter settings in Table 8.

	utility	distribution of Q_0	\bar{x}	parameters of Q_0	parameters of utility
(a)	exponential	uniform	0.3	$k = 1, k_0 = 0$	$p = 0.6$
(b)	exponential	exponential	0.3	$\alpha = 1.5, k_0 = 0$	$p = 0.6$
(c)	log	normal	1.8	$\mu_0 = 5, \sigma_0 = 1$	–
(d)	log	uniform	1.4	$k = 10, k_0 = 0$	–
(e)	piecewise	log-normal	3.5	$\mu_0 = -1, \sigma_0 = 3, k_0 = 2.3$	$p_1 = q_1 = 0.6, p_2 = 0.8, q_2 = 0.9, \lambda_1 = 1, \lambda_2 = 2$
(f)	piecewise	exponential	1.3	$\alpha = 0.7, k_0 = 2.3$	$p_1 = q_1 = 0.6, p_2 = 0.8, q_2 = 0.9, \lambda_1 = 1, \lambda_2 = 2$

Table 8: Parameter setting in Figures 4-5.

Applying the Algorithm 1, we obtain the numerical results in Table 9 and plot Figures 4-5, where each panel illustrates the structure of the correction function $y_{\text{sub}}(\cdot)$ and the Poor-Performance-Region Algorithm (PPRA) solution.

	poor performance region C	partition parameter	λ	λ_{cla}
(a)	(0.8803, 1)	$t_1 = 1$	$\lambda = 1.5540$	$\lambda_{\text{cla}} = 1.4429$
(b)	(0.8904, 1)	$t_1 = 1$	$\lambda = 1.5498$	$\lambda_{\text{cla}} = 1.4429$
(c)	(0.4608, 1)	$t_1 = 1$	$\lambda = 0.6497$	$\lambda_{\text{cla}} = 0.5556$
(d)	(0.0426, 0.7236)	$t_1 = 0.1766$	$\lambda = 0.8260$	$\lambda_{\text{cla}} = 0.7143$
(e)	$(0, 0.2419) \cup (0.8930, 1)$	$t_2 = 1, t_1 = 0.0049$	$\lambda = 1.7002$	$\lambda_{\text{cla}} = 0.9005$
(f)	(0.3902, 1)	$t_1 = 1$	$\lambda = 1.7930$	$\lambda_{\text{cla}} = 1.5516$

Table 9: Numerical results in Figures 4-5.

Later, we would clarify the structural behavior of the correction function $y_{\text{sub}}(\cdot)$. The numerical experiments yield the following explanations and financial insights:

1. Figure 4 (a)-(b)-(c): In bad market scenario, the correction function $y_{\text{sub}}(\cdot)$ satisfies $y_{\text{sub}}(\cdot) = y_0(\cdot)$, therefore, the PPRA wealth will coincide with the benchmark wealth. In this scenario, the benchmark serves as a risk-control mechanism, which is similar to Figure 2 (a)-(b)-(d).
2. Figure 4 (c)-(f): Compared with Figure 4 (a)-(b), the region where $y_{\text{sub}}(\cdot) = y_0(\cdot)$ expands. Hence, under relatively stagnant or bad market scenario, the PPRA wealth tends to coincide with the benchmark wealth. In such scenario, the SSD constraint plays a more prominent role by ensuring a benchmark wealth to reduce risk.
3. Figure 5 (d): The correction function $y_{\text{sub}}(\cdot) = y_0(\cdot)$ over certain intermediate intervals, causing the PPRA wealth to coincide with the benchmark in mid-range market scenario, as shown in (d)-Right.
4. Figure 5 (e): The correction function $y_{\text{sub}}(\cdot) = y_0(\cdot)$ at both endpoints of the interval $(0, 1)$. This implies the PPRA wealth must coincide with the benchmark wealth in both extremely bad and exceptionally

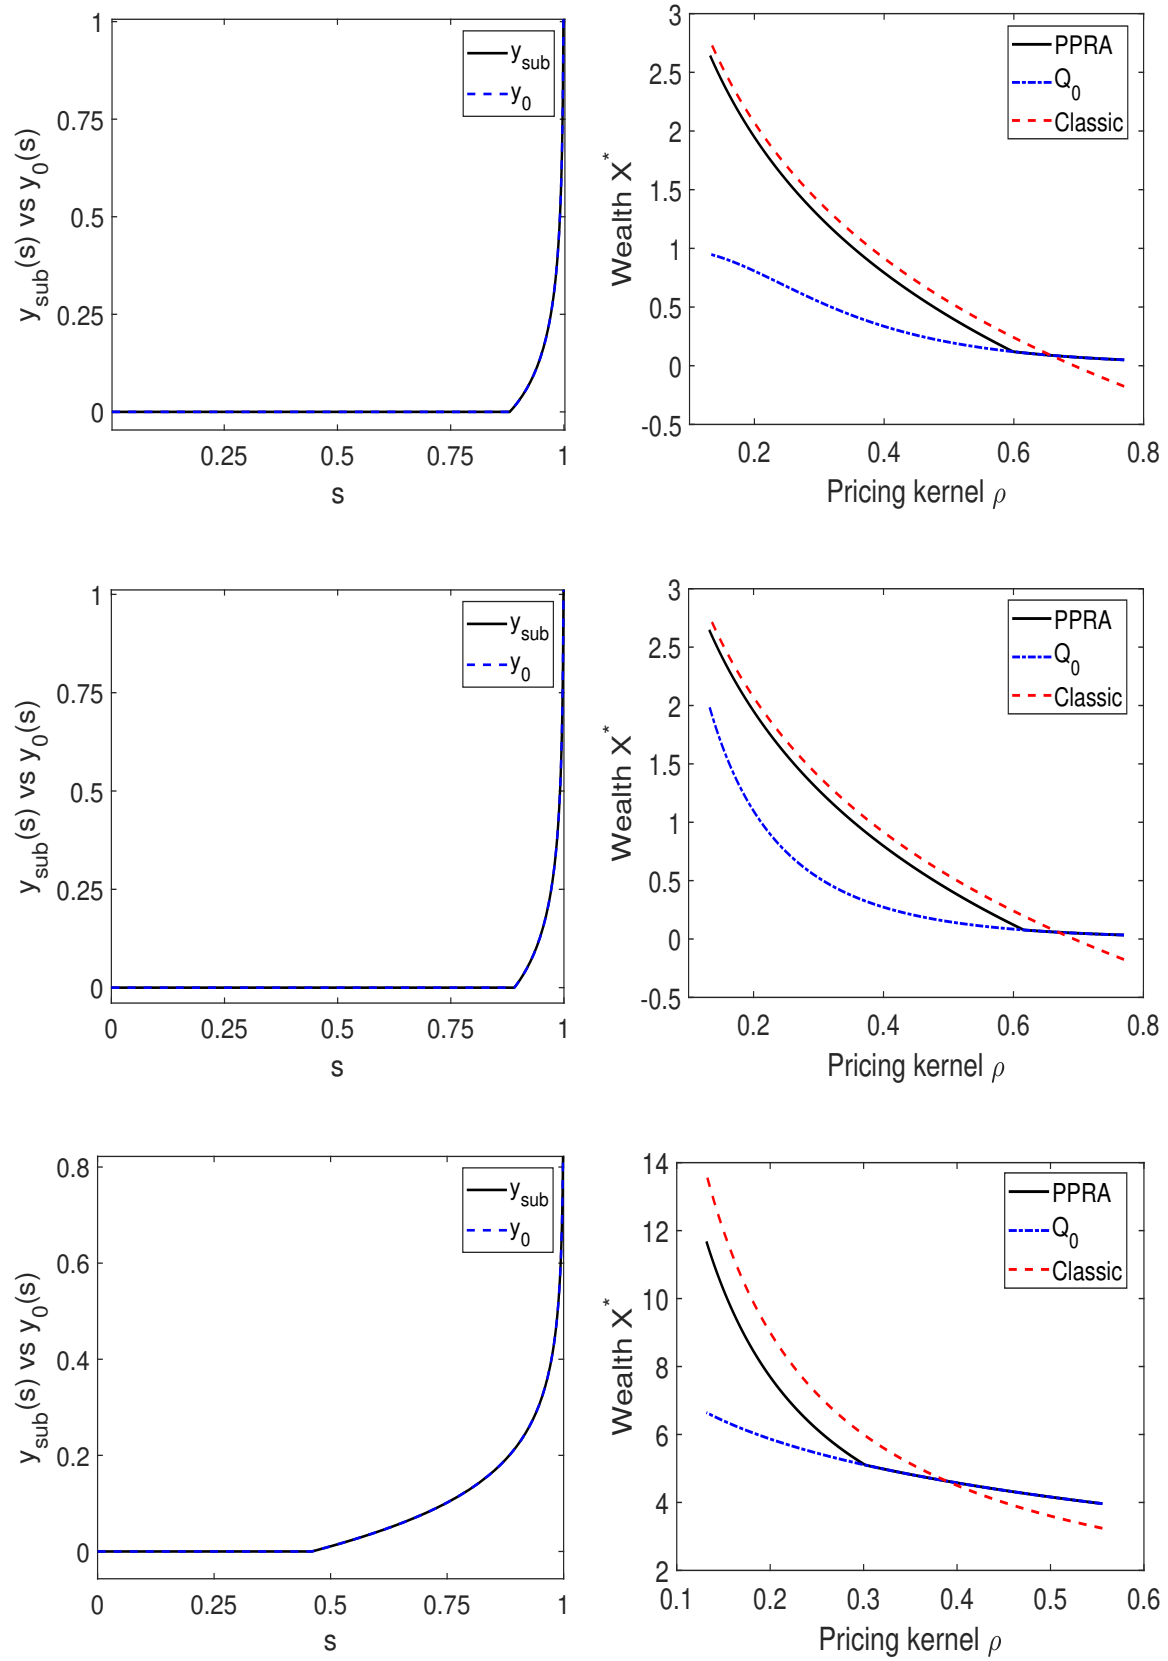

Figure 4: Setting (a)-(b)-(c).

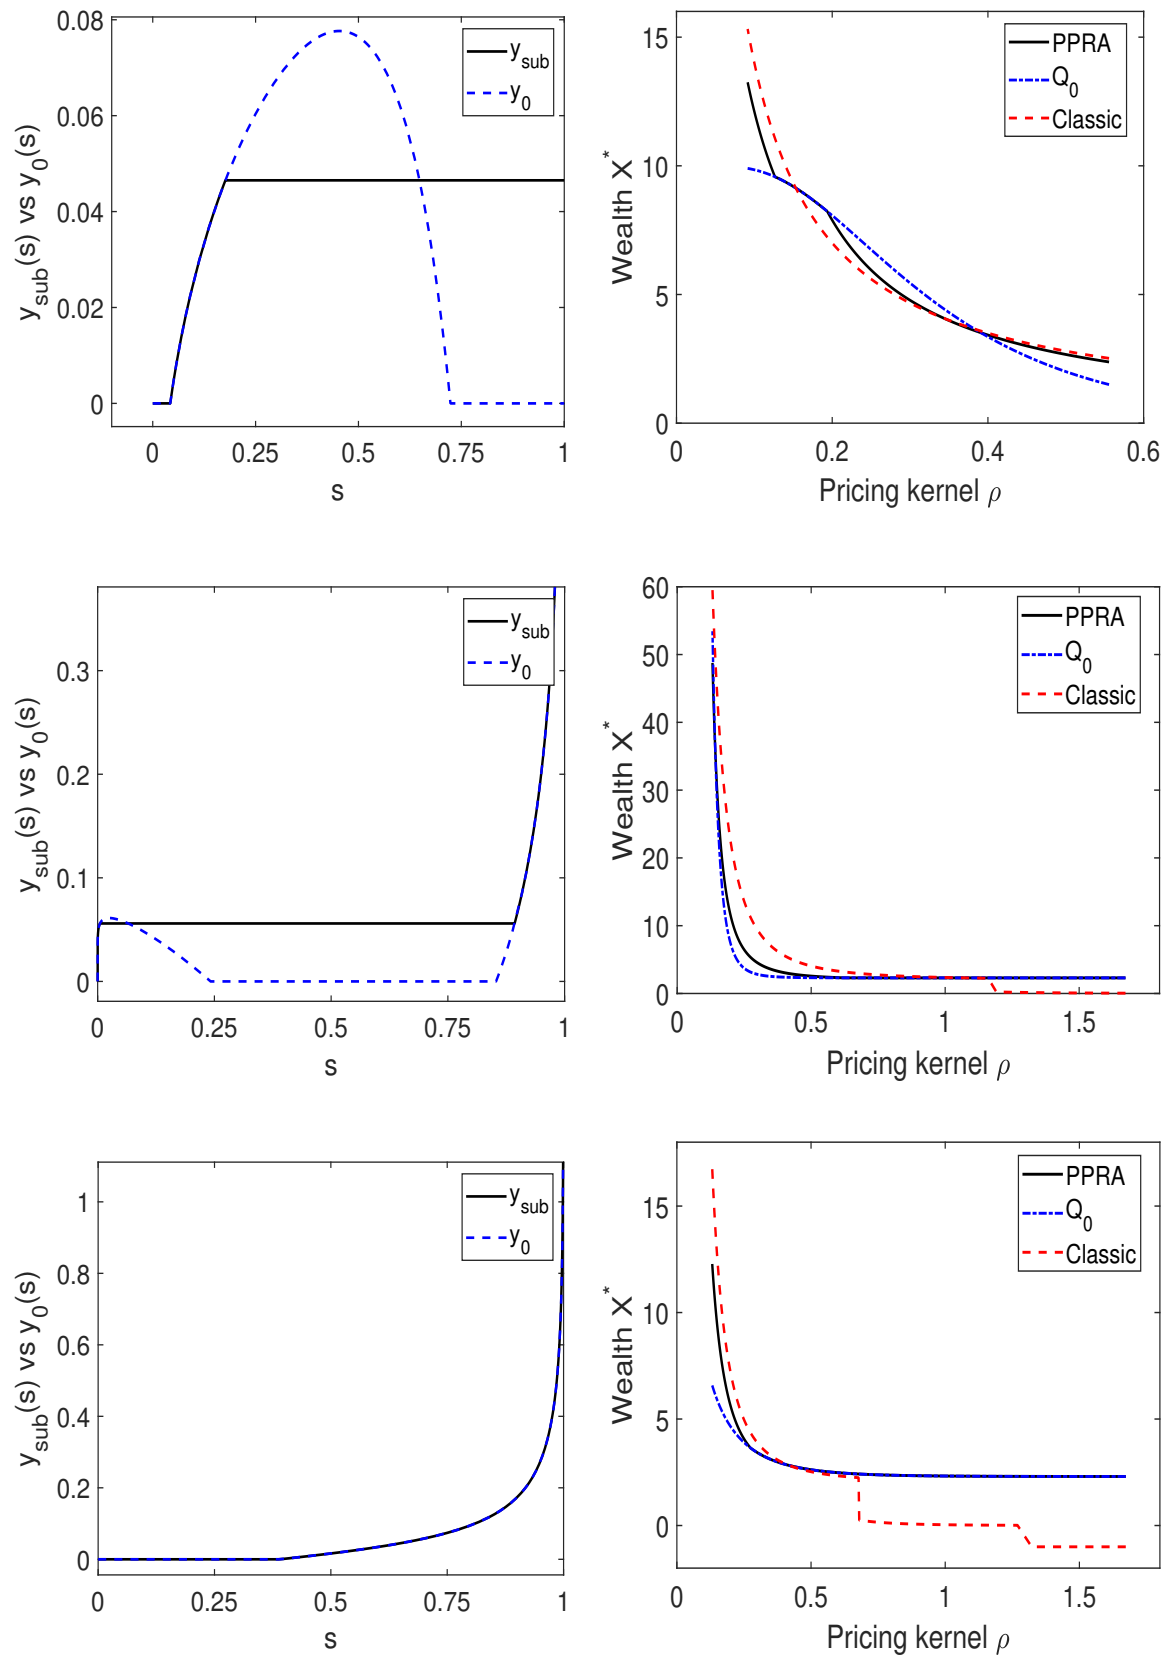

Figure 5: Setting (d)-(e)-(f).

favorable market scenarios.

In Figure 5 (e), we can observe how Steps 8-12 of Algorithm 1 ensure that the constructed function $y_{\text{sub}}(\cdot)$ remains non-decreasing on $(0, 1)$. The key idea is to modify the construction of $g_i(t)$ in Eq. (19) so that both monotonicity requirement of $y_{\text{sub}}(\cdot)$ and the condition $z^*(\cdot) \leq 0$ is satisfied throughout the region in which $y_{\text{sub}}(\cdot)$ is updated. In this example, the interval where $y_{\text{sub}}(\cdot) = y_{\text{sub}}(t_1)$ is extended into the region covered by the previous iteration (i.e., the first iteration), updating the original $y_{\text{sub}}(\cdot)$ in this region.

Across various combinations of the utilities and the benchmark quantiles Q_0 , we observe that the poor-performance region typically consists of one or two disjoint intervals. The proposed algorithm exhibits strong adaptability under these diverse settings, effectively identifying the sub-optimal solution in most cases. At the same time, our algorithm is able to handle certain special cases in which the original piecewise construction fails to guarantee monotonicity. By modifying the construction of $g_i(t)$, the algorithm provides a valid sub-optimal solution and, as a result, restores monotonicity and extends the applicability of our approach to more complex configurations.

6 Algorithm-Guided Piecewise-Neural-Network Framework

In this section, we propose a novel approach to solve the SSD Problem (14) by designing a piecewise-neural-network-framework combined with Algorithm 1. The key observation is that in Algorithm 1, the poor performance region C defined in Eq. (27) and the construction of the correction function $y_{\text{sub}}(\cdot)$ provide valuable structural information about the optimal solution, thereby guiding the design of an effective neural network framework.

We begin by applying Algorithm 1, which yields a correction function $y_{\text{sub}}(\cdot)$. Using $y_{\text{sub}}(\cdot)$, we derive a sub-optimal solution $Q_{\text{sub}}(\cdot)$ as presented in Eq. (24). To design a neural network framework, the key idea is that we use the structure information of the derived $Q_{\text{sub}}(\cdot)$ to build a piecewise-neural-network framework. Then we apply this framework to train a solution for Problem (14).

6.1 Model Setting

The optimization problem to be approximated by the neural network is formulated as follows:

$$\max_{Q \in \mathcal{Q}_2(Q_0)} \int_0^1 U(Q(s))ds \quad \text{s.t.} \quad \int_0^1 Q(s)Q_\rho(1-s)ds \leq \bar{x}, \quad (39)$$

which is identical to Problem (15).

Based on Algorithm 1, we obtain the suboptimal solution $Q_{\text{sub}}(\cdot)$ as given in Eq. (24), which exhibits a piecewise structure. Specifically, $Q_{\text{sub}}(\cdot)$ can be expressed as

Algorithm 2 Algorithm-guided piecewise-neural-network framework for SSD Problem (39)

- 1: Implement Algorithm 1 and get the sub-optimal solution structure as Eq. (24). Using the partition intervals $(s_k, s_{k+1}]$ defined in Eq. (40), initialize the neural network architecture as follows:

$$Q_\theta(s) = \begin{cases} f_{\theta_0}^{(0)}(\mathbf{s}_{\text{feat}}(s)), & s \in (s_0, s_1], \\ f_{\theta_1}^{(1)}(\mathbf{s}_{\text{feat}}(s)), & s \in (s_1, s_2], \\ \vdots \\ f_{\theta_K}^{(K)}(\mathbf{s}_{\text{feat}}(s)), & s \in (s_K, s_{K+1}), \end{cases} \quad (34)$$

where $f_\theta^{(k)}$ denotes the k -th neural sub-network parameterized by θ_k , the parameters of the integrated network Q are denoted as $\theta = \{\theta_0, \theta_1, \dots, \theta_K\}$. $\mathbf{s}_{\text{feat}}(s)$ represents the Fourier feature embedding of the scalar input s defined as

$$\mathbf{s}_{\text{feat}}(s) = [\sin(2\pi s), \sin(4\pi s), \cos(2\pi s), \cos(4\pi s)]^\top \in \mathbb{R}^4. \quad (35)$$

- 2: Define a prior function as follows:

$$\phi(s) = \begin{cases} I(Q_\rho(1-s)), & s \in (s_0, s_1], \\ Q_0(s), & s \in (s_1, s_2], \\ \vdots \\ I(Q_\rho(1-s)), & s \in (s_K, s_{K+1}). \end{cases} \quad (36)$$

- 3: For each interval, update the sub-network output with the analytic prior term and activate the integrated network $Q_\theta(\cdot)$ as follows:

$$Q_\theta(s) \leftarrow Q_\theta(s) + \phi(s), \quad Q_\theta(s) \leftarrow \text{ReLU}(Q_\theta(s)).$$

- 4: Define the objective function as the expected utility from Eq. (39). Since the integral cannot be computed analytically, we approximate it by uniformly sampling n points $s_i \in (0, 1)$ and compute

$$\mathcal{L}_{\text{obj}}(\theta) = \frac{1}{n} \sum_{i=1}^n U(Q_\theta(s_i)). \quad (37)$$

- 5: Take the budget constraint (C_1) and SSD constraint (C_2) as the penalty of the loss function. Define

$$C_1 = \frac{1}{n} \sum_{i=1}^n Q_\theta(s_i) Q_\rho(1-s_i), \quad C_2 = \max \left\{ 0, \max_{k=1, \dots, n} \left[\frac{1}{n} \sum_{i=1}^k Q_0(s_i) - \frac{1}{n} \sum_{i=1}^k Q_\theta(s_i) \right] \right\}.$$

- 6: Add weights w_1, w_2 to C_1, C_2 and calculate the loss function as follows

$$\mathcal{L}_{\text{p1}} = w_1 (C_1 - \bar{x})^2, \quad \mathcal{L}_{\text{p2}} = w_2 \cdot C_2, \quad (38)$$

$$\mathcal{L}_{\text{total}}(\theta) = -\mathcal{L}_{\text{obj}}(\theta) + \mathcal{L}_{\text{p1}} + \mathcal{L}_{\text{p2}}.$$

- 7: Next, start the training process.

Require: Neural sub-networks $\{f_\theta^{(k)}\}_{k=0}^K$, pricing kernel function $Q_\rho(\cdot)$, benchmark function $Q_0(\cdot)$, utility function $U(\cdot)$, budget \bar{x} , sample size n , learning rate η , number of Adam steps A_s , penalty weights w_1, w_2 .

Ensure: Trained network $Q_\theta(s)$.

- 8: Sample $s_i \in (0, 1)$, $i = 1, \dots, n$.
- 9: Compute Fourier features \mathbf{s}_{feat} as Eq. (35).
- 10: **for** $k = 0$ to K **do**
- 11: Initialize each sub-network: $f_{\theta_k}^{(k)}(\mathbf{s}_{\text{feat}}(s_i))$.
- 12: Compute analytic prior $\phi(s_i)$ as Eq. (36).
- 13: **end for**
- 14: Merge the sub-networks to an integrated network $Q_\theta(s)$ as Eq. (34).
- 15: Activate the network: $Q_\theta(s) \leftarrow \text{ReLU}(Q_\theta(s))$.
- 16: **for** $i = 0$ to A_s **do**
- 17: Compute the objective function: $\mathcal{L}_{\text{obj}}(\theta) = \frac{1}{n} \sum_{i=1}^n U(Q_\theta(s_i))$.
- 18: Compute constraint penalties \mathcal{L}_{p1} and \mathcal{L}_{p2} as Eq. (38).
- 19: Compute the total loss in current iteration: $\mathcal{L}_{\text{total}}(\theta) = -\mathcal{L}_{\text{obj}}(\theta) + \mathcal{L}_{\text{p1}} + \mathcal{L}_{\text{p2}}$.
- 20: **Adam update:** $\theta \leftarrow \theta - \eta \nabla_\theta \mathcal{L}_{\text{total}}(\theta)$.
- 21: **end for**
- 22: **return** Trained network $Q_\theta(s)$.

$$Q_{\text{sub}}(s) = \begin{cases} I(\lambda(Q_\rho(1-s) - y(\cdot))), & s \in (s_0, s_1], \\ Q_0(s), & s \in (s_1, s_2], \\ \vdots & \\ I(\lambda(Q_\rho(1-s) - y(\cdot))), & s \in (s_K, s_{K+1}), \end{cases} \quad (40)$$

where $s_0 = 0, s_{K+1} = 1$.

Following this structure, we construct a set of neural sub-networks $\{f_{\theta_k}^{(k)}\}_{k=0}^K$ to approximate each interval respectively. The main design considerations are summarized as follows:

- a In Step 1, the piecewise formulation ensures that $Q_\theta(s)$ inherits the partition interval of $Q_{\text{sub}}(\cdot)$, enabling the network to better capture the structural behavior of the optimal solution. Specifically, each sub-network $f_{\theta_k}^{(k)}$ is a fully connected feedforward network with 8 hidden layers, each consisting of 256 neurons with Tanh activations.
- b In Step 2, we introduce an analytical prior term into each sub-network $f_{\theta_k}^{(k)}$. The design of $\phi(s)$ is inspired by the structure of $Q_{\text{sub}}(\cdot)$, preserving essential information from the solution of Algorithm 1 as a prior function and helps the network to capture the intrinsic information of the optimal solution.
- c In Steps 5-6, we square the violation of the budget constraint to represent its penalty, ensuring the budget stays close to \bar{x} . For the SSD constraint, we penalize the maximal violation to strictly enforce its satisfaction. The relative importance of satisfying the constraint during training can be adjusted by tuning its associated weight w_1, w_2 .
- d In Steps 8-22, the approximation accuracy of the objective function and constraints can be improved by increasing the number of sampled points n . The Adam optimizer is used to update the network parameters, and the number of Adam steps A_s determines how many gradient-based updates are performed during training, thus controlling the convergence of the network.

6.2 Experimental Results

To validate the model, we first conduct experiments under conditions in which the optimal solution $Q^*(\cdot)$ is available. The optimality is because Algorithm 1 results numerically satisfy the characterization in Theorem 2. We follow the setup in Section 5.4, which considers both the exponential utility and log utility under a linear SSD constraint quantile Q_0 (Table 8 (a)(c)).

We follow the steps in Algorithm 2 to get a trained neural network Q_θ , and the results are summarized in Table 10.

Here are some illustrations of the neural network results:

1. Figure 6 (i)-(ii) Left: Compared with Figure 4 (a) and Figure 5 (d), the algorithm-guided piecewise-neural-network framework successfully preserves the structure features of the optimal solution, achiev-

	utility	distribution of Q_0	optimal value	neural network value
(i)	exponential	uniform	-0.8965	-0.8990
(ii)	log	uniform	1.4781	1.4686

Table 10: Objective value for neural network approximation.

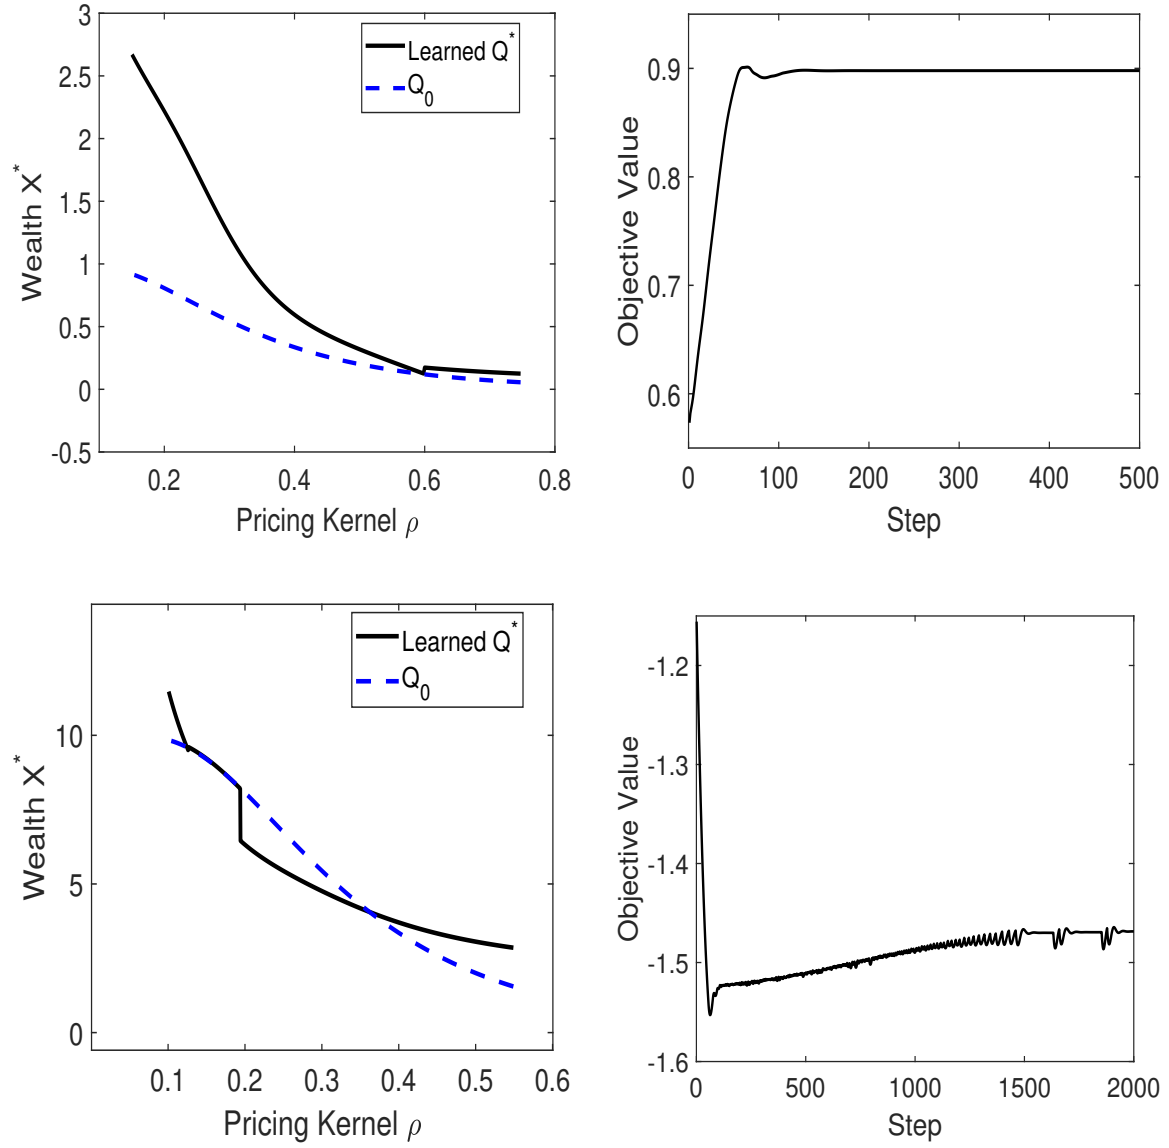

Figure 6: Neural network approximation results.

ing a close match.

2. Convergence behavior: The network typically converges within 100-2000 steps. As shown in Table 10, our algorithm achieves high numerical accuracy relative to the optimal solution, which is reflected in the objective value $\int_0^1 U(Q(s))ds$ in Problem (39).
3. Figure 6 (i)-(ii) Right: The convergence speed depends on the number of sub-networks: the exponential case uses 2 sub-networks, while the log case uses 3, which also reflects the problem complexity. In simpler cases (Figure 6 (i)), the convergence curves are smooth and rapid because the two constraints in Problem (39) are quickly satisfied. In more complex cases (Figure 6 (ii)), the network spends more time mitigating constraint penalties, resulting in slower convergence.

Here we come to the conclusion that our approach, first deriving a sub-optimal solution via the proposed algorithm and then leveraging it to guide the neural network design, effectively captures the essential properties of the optimal solution and provides stable, high-quality performance for the SSD problem.

Extending to non-concave utility functions introduces a substantially more challenging problem. The difficulty stems from several factors. First, the optimization is infinite-dimensional over the space of admissible allocation functions, meaning that the solution is a functional rather than a finite-dimensional vector. Second, in the presence of SSD constraint and budget constraint, the feasible set becomes highly restricted and non-convex, which further complicates convergence.

Remarkably, our algorithm-guided piecewise-neural-network framework remains stable under these challenging conditions and achieves rapid convergence. By leveraging sub-optimal solutions obtained from our proposed Algorithm 1 as analytic priors and structuring the network in a piecewise manner, the framework effectively reduces the functional search space and guides the optimization toward regions that respect the SSD constraints. In contrast, a standard monolithic-neural-network (non-piecewise) framework exhibits substantially slower convergence, often requiring tens of times more training steps to reach convergence.

To illustrate this, we consider an S-shaped utility following the setup in Section 5.3 (Table 4 (b)). Solutions obtained with our Algorithm 2 are compared against those from a standard monolithic-neural-network framework using identical parameter settings.

	network	neural network value	C_1 satisfied steps	C_2 satisfied steps
(i)	piecewise	14.7531	83	10
(ii)	standard	12.0320	10950	4279

Table 11: Convergence step and constraint satisfied step.

Here, we illustrate the convergence behavior of different neural network designs:

1. Table 11: The neural network value corresponds to the objective value $\int_0^1 U(Q(s))ds$ in Problem (39). The table also reports the minimum number of steps required to satisfy the SSD and budget constraints for each network design.

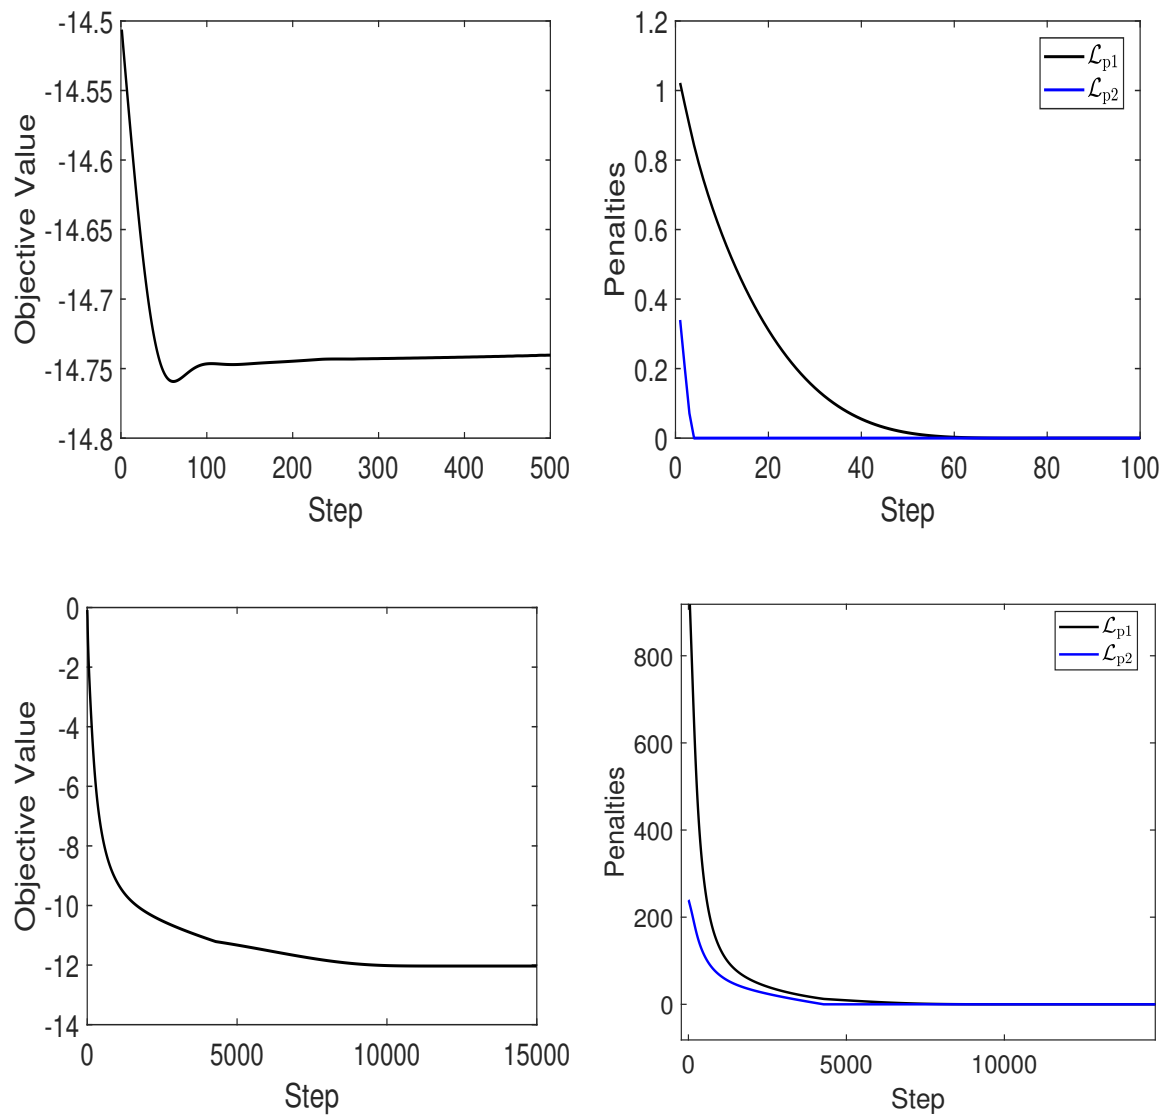

Figure 7: Convergence behavior and penalty updates.

2. Figure 7: Our algorithm-guided piecewise-neural-network framework reaches near-convergence in roughly 300 Adam steps, whereas a standard monolithic-neural-network requires approximately 10,000 steps to achieve comparable near-convergence. This dramatic acceleration highlights the efficiency of our approach. Furthermore, our piecewise framework achieves a higher sub-optimal objective value compared with the standard framework, indicating that the standard framework is prone to getting trapped in local optima, while our piecewise framework can avoid such traps and attain superior performance.
3. Table 11 (i) vs. (ii): The significant speedup under the piecewise framework primarily stems from rapid satisfaction of the penalty terms. By incorporating analytic prior inspired from Algorithm 1 into the network design, our piecewise framework enforces the SSD and budget constraints more efficiently, allowing the neural network to converge quickly while maintaining better approximation of the sub-optimal solution.

In summary, our study demonstrates the effectiveness of the algorithm-guided piecewise-neural-network framework for solving the SSD problem. For cases where an analytical optimal solution exists, our framework achieves results that closely match the optimal solution both numerically and structurally, indicating its high precision. From the perspective of convergence, our framework significantly accelerates the optimization process and is capable of escaping local optima, thereby attaining superior objective value compared with the standard monolithic-neural-network framework. These findings highlight the efficiency and robustness of our approach across different problem settings, and suggest strong potential for extension to more complex scenarios.

7 Conclusion

We study a utility maximization problem under stochastic dominance constraints. Starting from an S-shaped utility function, we derive the explicit optimal solution without a liquidation boundary under first-order stochastic dominance (FSD) constraints. For the more challenging SSD problem, particularly under non-concavity, obtaining an explicit optimal solution is inherently difficult. Motivated by the structural properties of the analytical theorem in the concave case, we introduce a Poor-Performance-Region Algorithm (PPRA). This algorithm efficiently identifies the candidate structure that a potential optimal solution should satisfy and proves effective in the vast majority of cases. In addition, extensive numerical experiments illustrate how the algorithm operates, confirm its broad applicability, and demonstrate its capability to handle the few exceptional cases.

Building on the structural insights provided by the PPRA, we further recognize the potential of neural networks in tackling SSD problems under non-concavity. While neural networks offer strong approximation capabilities, their direct application often suffers from slow convergence and severe sensitivity to local optima induced by non-concavity. By leveraging the PPRA’s ability to capture the essential structure of the optimal solution, we develop an algorithm-guided piecewise-neural-network framework that integrates these struc-

tural cues into the learning process. Compared with a standard neural-network approach, this framework achieves significantly faster convergence and effectively avoids undesirable local minima, thereby delivering consistently superior solution quality.
