

# Regular functional covering numbers

Apostolos Giannopoulos and Natalia Tzotziou

## Abstract

We establish the existence of a *regular* functional  $M$ -position, in the sense of Pisier, for geometric log-concave functions. This provides a functional analogue of Pisier's regular  $M$ -positions for convex bodies and yields uniform control of covering numbers at all scales. Specifically, we show that every isotropic geometric log-concave function  $f : \mathbb{R}^n \rightarrow [0, \infty)$  satisfies, for all  $t \geq 1$ ,

$$\max\left\{N(f, t \odot g), N(f^*, t \odot g), N(g, t \odot f), N(g, t \odot f^*)\right\} \leq \exp\left(\frac{\gamma_n^2 n}{t}\right),$$

where  $f^*$  denotes the Legendre dual of  $f$ ,  $(t \odot f)(x) = f(x/t)$  is the  $t$ -homothety of  $f$ , and  $\gamma_n \leq c(\ln n)^2$ . Our result shows that the isotropic position of a log-concave function already provides an almost 1-regular functional  $M$ -position.

## 1 Introduction

The study of covering numbers lies at the intersection of asymptotic geometric analysis and high-dimensional probability. Sharp covering estimates have found important applications in analysis, geometry, probability and combinatorics. Milman's theory of  $M$ -positions reveals that every convex body has a highly regular affine image whose covering behavior, and that of its polar, exhibit near-optimal exponential bounds. Recent developments have extended these ideas to log-concave functions, uncovering a rich functional counterpart to classical convex-geometric notions.

The purpose of this paper is to show that geometric log-concave functions admit a regular functional  $M$ -position, in the sense of Pisier, and that, remarkably, the isotropic position already provides such a regular position. In particular, isotropic log-concave functions satisfy almost 1-regular covering estimates at all scales.

Let  $K$  and  $T$  be convex bodies in  $\mathbb{R}^n$ . The covering number  $N(K, T)$  is the smallest number of translates of  $T$  needed to cover  $K$ :

$$N(K, T) = \min\left\{N \in \mathbb{N} : \exists x_1, \dots, x_N \in \mathbb{R}^n \text{ such that } K \subseteq \bigcup_{j=1}^N (x_j + T)\right\}.$$

A classical theorem of V. Milman [23] asserts that every centered convex body  $K$  can be placed in  $M$ -position, namely there exists a linear image  $\tilde{K}$  with  $\text{vol}_n(\tilde{K}) = \text{vol}_n(B_2^n)$  such that

$$(1.1) \quad \max\left\{N(\tilde{K}, B_2^n), N(B_2^n, \tilde{K}), N(\tilde{K}^\circ, B_2^n), N(B_2^n, \tilde{K}^\circ)\right\} \leq \exp(\beta n),$$

for an absolute constant  $\beta > 0$ , where  $B_2^n$  is the Euclidean unit ball and  $\tilde{K}^\circ$  is the polar body of  $\tilde{K}$ . Background material on convex bodies and log-concave functions is collected in Section 2.

The framework of covering numbers was extended to functions by Artstein-Avidan and Slomka in [3] (see also the earlier work [2] of Artstein-Avidan and Raz). Given measurable  $f, g : \mathbb{R}^n \rightarrow [0, \infty)$ , the functional covering number of  $f$  by  $g$  is defined by

$$N(f, g) = \inf\left\{\mu(\mathbb{R}^n) : \mu * g \geq f\right\},$$

where the infimum runs over non-negative Borel measures  $\mu$  satisfying

$$(\mu * g)(x) = \int_{\mathbb{R}^n} g(x-t) d\mu(t) \geq f(x) \quad \text{for all } x \in \mathbb{R}^n.$$

Let  $LC_g(\mathbb{R}^n)$  denote the class of geometric log-concave functions; these are the upper semi-continuous log-concave functions  $f : \mathbb{R}^n \rightarrow [0, \infty)$  with  $f(0) = \|f\|_\infty = 1$ . If  $f = e^{-\varphi} \in LC_g(\mathbb{R}^n)$ , its Legendre dual is  $f^* = e^{-\mathcal{L}\varphi}$ , where

$$\mathcal{L}\varphi(x) = \sup_{y \in \mathbb{R}^n} \{ \langle x, y \rangle - \varphi(y) \}$$

is the Legendre transform of  $\varphi$ . In the functional setting, the dual function  $f^*$  plays a role analogous to that of the polar body in classical convex geometry: many geometric inequalities relating a convex body to its polar admit functional counterparts involving a log-concave function and its Legendre dual. A notable example is the functional Blaschke–Santaló inequality,

$$\int_{\mathbb{R}^n} \exp(-\varphi(x)) dx \cdot \int_{\mathbb{R}^n} \exp(-\mathcal{L}\varphi(x)) dx \leq (2\pi)^n.$$

The natural analogue of the Euclidean ball is the Gaussian

$$g(x) = \exp(-\tfrac{1}{2}|x|^2), \quad \text{for which } g^* = g.$$

Artstein-Avidan and Slomka [4] established the existence of a functional version of Milman’s  $M$ -position for geometric log-concave functions.

**Theorem 1.1** (Artstein–Slomka). *Let  $f : \mathbb{R}^n \rightarrow [0, \infty)$  be a geometric log-concave function. There exists  $T \in GL_n$  such that  $\tilde{f} = f \circ T$  satisfies  $\int \tilde{f} = (2\pi)^{n/2}$  and*

$$\max\{N(\tilde{f}, g), N(\tilde{f}^*, g), N(g, \tilde{f}), N(g, \tilde{f}^*)\} \leq C^n,$$

for an absolute constant  $C > 0$ .

In this work we establish the existence of a regular functional  $M$ -position, in the sense of Pisier, for geometric log-concave functions. Pisier [25] constructed an entire family of  $M$ -positions for any symmetric convex body  $K \subset \mathbb{R}^n$ , providing quantitative control of covering numbers at all scales.

**Theorem 1.2** (Pisier). *Let  $0 < \alpha < 2$  and let  $K \subset \mathbb{R}^n$  be a symmetric convex body. Then  $K$  has a linear image  $\tilde{K}$  such that*

$$\max\{N(\tilde{K}, tB_2^n), N(B_2^n, t\tilde{K}), N(\tilde{K}^\circ, tB_2^n), N(B_2^n, t\tilde{K}^\circ)\} \leq \exp(c(\alpha)n/t^\alpha)$$

for every  $t \geq c(\alpha)^{1/\alpha}$ , where  $c(\alpha) = O((2-\alpha)^{-\alpha/2})$  as  $\alpha \rightarrow 2^-$ .

A convex body satisfying the above is said to be in  $\alpha$ -regular  $M$ -position.

**Main results.** We prove that geometric log-concave functions admit an almost 1-regular functional  $M$ -position. Moreover, we show that the isotropic position already enjoys this regularity. Background material on isotropic convex bodies and isotropic log-concave functions is provided in Section 2. In our results, homothetic dilation of log-concave functions is given by

$$(t \odot f)(x) = f(x/t), \quad t > 0.$$

**Theorem 1.3.** *Let  $f : \mathbb{R}^n \rightarrow [0, \infty)$  be an isotropic geometric log-concave function. Then for every  $t \geq 1$ ,*

$$\max\left\{N(f, t \odot g), N(g, t \odot f^*)\right\} \leq \exp\left(\frac{\gamma_n^2 n}{t}\right),$$

and

$$\max\left\{N(f^*, t \odot g), N(g, t \odot f), \right\} \leq \exp\left(\frac{\delta_n^2 n}{t}\right),$$

where  $\gamma_n \leq c(\ln n)^2$  and  $\delta_n \leq c \ln n$ .

Thus the isotropic position yields a universal functional  $M$ -position whose regularity exponent is arbitrarily close to 1.

We outline the main ideas of the proof. To each isotropic  $f$  we associate the convex body

$$R_f := \{x \in \mathbb{R}^n : f(x) \geq \exp(-50n)\}.$$

One may compare  $R_f$  with the isotropic convex body  $K_{n+1}(f)$  introduced by K. Ball [7], and verify that their geometric distance is bounded by an absolute constant. We then use an observation of the second named author [28], based on E. Milman's sharp  $M^*$ -estimate [22] and the recent optimal  $M$ -estimate of Bizeul and Klartag [9] for isotropic convex bodies, to show that  $R_f$  satisfies almost 2-regular covering estimates. These geometric bounds are transferred to the functional covering numbers  $N(f, t \odot g)$  and  $N(g, t \odot f)$  using a decomposition of  $\exp(-50n\| \cdot \|_{R_f})$ , a corresponding decomposition of the Gaussian  $g$ , and basic structural properties of functional covering numbers.

A dual argument applies to the Legendre transform. A result of Fradelizi and Meyer [15] implies that

$$50n(R_f)^\circ \subseteq R_{f^*} \subseteq 100n(R_f)^\circ.$$

Combined with the Blaschke–Santaló and Bourgain–Milman inequalities, this yields analogous regularity for the covering numbers of  $R_{f^*}$ , and hence for  $N(f^*, t \odot g)$  and  $N(g, t \odot f^*)$ .

We also show that isotropic geometric log-concave functions satisfy the conclusion of Theorem 1.1. That is, the isotropic position already provides a universal functional  $M$ -position in the sense of Milman.

**Theorem 1.4.** *Let  $f : \mathbb{R}^n \rightarrow [0, \infty)$  be an isotropic geometric log-concave function.. Then,*

$$\max\left\{N(f, g), N(f^*, g), N(g, f), N(g, f^*)\right\} \leq C^n,$$

for an absolute constant  $C > 0$ .

The proof combines ideas from the proof of Theorem 1.1 in [4] with techniques employed in the proof of Theorem 1.3. Compared with Theorem 1.3, Theorem 1.4 yields sharper estimates for the covering numbers in the regime where  $t \geq 1$  is bounded above by a small power of  $\ln n$ . Thus, the isotropic position furnishes an efficient and robust functional  $M$ -position without requiring additional regularization assumptions.

Our second main result shows that similar regular estimates for the functional covering numbers hold true for another choice of the dual of  $f$ , which is based on the polarity transform. The polar function  $\varphi^\circ$  of a convex lower semi-continuous function  $\varphi : \mathbb{R}^n \rightarrow [0, \infty]$  with  $\varphi(0) = 0$  is defined by the  $\mathcal{A}$ -transform of  $\varphi$ :

$$\varphi^\circ(x) = (\mathcal{A}\varphi)(x) = \sup_{y \in \mathbb{R}^n} \frac{\langle x, y \rangle - 1}{\varphi(y)}.$$

The definition of the  $\mathcal{A}$ -transform appears in the book by Rockafellar [27, page 136], where it is also proved that it commutes with the Legendre transform. However, the polarity transform was introduced and studied in depth by Artstein-Avidan and Milman in [1] as the functional extension of convex-body polarity and plays a central role in functional versions of the Blaschke–Santaló and Bourgain–Milman inequalities.

Consider the geometric log-concave function  $f = e^{-\varphi}$ . A result of V. Milman and Rotem from [24] implies that if we consider the scaled polar function

$$\varphi_{\mathcal{A}}(x) = (50n)^2 \varphi^\circ(x/n)$$

and if we define  $f_{\mathcal{A}} = e^{-\varphi_{\mathcal{A}}}$  then

$$n(R_f)^\circ \subseteq R_{f_{\mathcal{A}}} \subseteq 2n(R_f)^\circ.$$

Using the same strategy as in the proof of Theorem 1.3 we show that  $f_{\mathcal{A}}$  also admits regular covering estimates.

**Theorem 1.5.** *Let  $f : \mathbb{R}^n \rightarrow [0, \infty)$  be an isotropic geometric log-concave function. Then for every  $t \geq 1$ ,*

$$N(g, t \odot f_{\mathcal{A}}) \leq \exp\left(\frac{\gamma_n^2 n}{t}\right) \quad \text{and} \quad N(f_{\mathcal{A}}, t \odot g) \leq \exp\left(\frac{\delta_n^2 n}{t}\right),$$

where  $\gamma_n \leq c(\ln n)^2$  and  $\delta_n \leq c \ln n$ .

We also obtain the corresponding analogue of Theorem 1.4.

**Theorem 1.6.** *Let  $f : \mathbb{R}^n \rightarrow [0, \infty)$  be an isotropic geometric log-concave function. Then,*

$$\max\{N(f, g), N(f_{\mathcal{A}}, g), N(g, f), N(g, f_{\mathcal{A}})\} \leq C^n,$$

for an absolute constant  $C > 0$ .

Together, Theorems 1.3 and 1.5 show that, in the isotropic position, a log-concave function  $f$  and its duals  $f^*$  and  $f_{\mathcal{A}}$  behave like well-balanced Gaussians at all scales. This establishes a functional analogue of Pisier's theorem on the existence of regular  $M$ -positions for convex bodies, and may have further applications in the analysis of log-concave functions.

For background on isotropic convex bodies and log-concave measures and functions, see [12]; for general information on the local theory of normed spaces, see [5, 6, 26].

## 2 Convex bodies and log-concave functions

We work in  $\mathbb{R}^n$ , equipped with the standard inner product  $\langle \cdot, \cdot \rangle$ . The corresponding Euclidean norm is denoted by  $|\cdot|$ , the Euclidean unit ball by  $B_2^n$ , and the Euclidean unit sphere by  $S^{n-1}$ . Volume in  $\mathbb{R}^n$  is denoted by  $\text{vol}_n$ , and we write  $\omega_n = \text{vol}_n(B_2^n)$  for the volume of the unit ball. We denote by  $\sigma$  the rotationally invariant probability measure on  $S^{n-1}$ .

Throughout the text, the symbols  $c, c', c_1, c_2, \dots$  denote absolute positive constants whose values may change from line to line. Whenever we write  $a \approx b$ , we mean that there exist absolute constants  $c_1, c_2 > 0$  such that  $c_1 a \leq b \leq c_2 a$ . Similarly, for subsets  $K, T \subseteq \mathbb{R}^n$ , we write  $K \approx T$  if  $c_1 K \subseteq T \subseteq c_2 K$  for some absolute constants  $c_1, c_2 > 0$ .

**2.1. Convex bodies.** A convex body in  $\mathbb{R}^n$  is a compact convex set  $K$  with nonempty interior. It is called symmetric if  $K = -K$ , and centered if its barycenter  $\text{bar}(K) = \frac{1}{\text{vol}_n(K)} \int_K x \, dx$  is at the origin. If  $K$  and  $T$  are two convex bodies in  $\mathbb{R}^n$  that contain the origin in their interior, their geometric distance  $d_G(K, T)$  is defined by

$$d_G(K, T) = \inf\{ab : a, b > 0, K \subseteq bT \text{ and } T \subseteq aK\}.$$

The radial function of a convex body  $K$  with  $0 \in \text{int}(K)$  is defined by  $\rho_K(x) = \max\{t > 0 : tx \in K\}$  for  $x \neq 0$ , and the support function of  $K$  is given by  $h_K(y) = \max\{\langle x, y \rangle : x \in K\}$ ,  $y \in \mathbb{R}^n$ . The volume radius of  $K$  is

$$\text{vrad}(K) = r_K = \left( \frac{\text{vol}_n(K)}{\text{vol}_n(B_2^n)} \right)^{1/n}.$$

The polar body of a convex body  $K$  with  $0 \in \text{int}(K)$  is defined as

$$K^\circ = \{x \in \mathbb{R}^n : \langle x, y \rangle \leq 1 \text{ for all } y \in K\}.$$

The Blaschke–Santaló inequality states that if  $K$  is a convex body in  $\mathbb{R}^n$  such that either  $\text{bar}(K) = 0$  or  $\text{bar}(K^\circ) = 0$ , then

$$\text{vol}_n(K) \text{vol}_n(K^\circ) \leq \omega_n^2.$$

In the opposite direction, the Bourgain–Milman inequality guarantees that if  $K$  is a convex body in  $\mathbb{R}^n$  with  $0 \in \text{int}(K)$ , then

$$\text{vol}_n(K) \text{vol}_n(K^\circ) \geq c^n \omega_n^2,$$

where  $c > 0$  is an absolute constant. These classical results can be found, for example, in [5].

**2.2. Log-concave functions.** A function  $f : \mathbb{R}^n \rightarrow [0, \infty)$  is called log-concave if it can be written in the form  $f = e^{-\varphi}$ , where  $\varphi : \mathbb{R}^n \rightarrow (-\infty, \infty]$  is a proper, lower semi-continuous (l.s.c.) convex function. Properness means that  $\text{dom}(\varphi) := \{x \in \mathbb{R}^n : \varphi(x) < \infty\} \neq \emptyset$ , and l.s.c. convexity ensures that  $f$  is upper semi-continuous and satisfies the classical log-concavity inequality  $f((1-\lambda)x + \lambda y) \geq f(x)^{1-\lambda} f(y)^\lambda$  for all  $x, y \in \mathbb{R}^n$ ,  $\lambda \in (0, 1)$ .

We call  $f = e^{-\varphi}$  a geometric log-concave function if it also satisfies the normalization

$$f(0) = \|f\|_\infty = 1,$$

which is equivalent to requiring that the associated convex function  $\varphi$  satisfies

$$\varphi : \mathbb{R}^n \rightarrow [0, \infty], \quad \varphi(0) = 0,$$

together with properness, convexity, and lower semi-continuity (these are the geometric convex functions). We denote by  $LC_g(\mathbb{R}^n)$  the class of all such geometric log-concave functions.

For any convex body  $K \subset \mathbb{R}^n$ , the indicator function  $\mathbb{1}_K$  is a geometric log-concave function. Indeed, let  $\mathbb{1}_K^\infty$  be the convex indicator of  $K$ ,

$$\mathbb{1}_K^\infty(x) = \begin{cases} 0, & x \in K, \\ \infty, & x \notin K, \end{cases}$$

which is a proper l.s.c. convex function with  $\mathbb{1}_K^\infty(0) = 0$  whenever  $0 \in K$ . Then  $\mathbb{1}_K = \exp(-\mathbb{1}_K^\infty)$ .

For  $t > 0$  and a log-concave function  $f$ , the functional homothety is defined by

$$(t \odot f)(x) = f(x/t),$$

which corresponds to replacing  $\varphi$  by  $\varphi_t(x) = \varphi(x/t)$ . This transformation respects log-concavity and is a natural functional counterpart of geometric dilation.

Let  $\varphi : \mathbb{R}^n \rightarrow [0, \infty]$  be a geometric convex function. The Legendre transform of  $\varphi$  is

$$\mathcal{L}\varphi(x) = \sup_{y \in \mathbb{R}^n} \{\langle x, y \rangle - \varphi(y)\}.$$

It is always a convex, l.s.c. function, and satisfies the involution property  $\mathcal{L}(\mathcal{L}\varphi) = \varphi$  if  $\varphi$  is proper, l.s.c., convex. The Legendre dual of  $f = e^{-\varphi}$  is then defined as

$$f^*(x) = \exp(-\mathcal{L}\varphi(x)).$$

The fundamental example of a self-dual log-concave function is the Gaussian

$$g(x) = \exp(-\tfrac{1}{2}|x|^2),$$

which satisfies

$$\int_{\mathbb{R}^n} g(x) dx = (2\pi)^{n/2}, \quad g^* = g.$$

Given two log-concave functions  $f = e^{-\varphi}$  and  $g = e^{-\psi}$ , we define the sup-convolution or Asplund product of  $f$  and  $g$  by

$$(f \star g)(x) = \sup_{y \in \mathbb{R}^n} f(y) g(x - y) = \exp(-(\varphi \square \psi)(x)),$$

where the inf-convolution of two convex functions  $\varphi$  and  $\psi$  is

$$(\varphi \square \psi)(x) = \inf_{y \in \mathbb{R}^n} \{\varphi(y) + \psi(x - y)\}.$$

In view of the identity  $\mathcal{L}(\varphi \square \psi) = \mathcal{L}\varphi + \mathcal{L}\psi$ , the operation  $f \star g$  allows us to define the analogue of Minkowski addition of log-concave functions.

The polar (or  $\mathcal{A}$ -transform) of  $\varphi$  is defined by

$$\varphi^\circ(x) = (\mathcal{A}\varphi)(x) = \sup_{y \in \mathbb{R}^n} \frac{\langle x, y \rangle - 1}{\varphi(y)}.$$

This transform is a functional analogue of the classical polarity of convex bodies. If  $\varphi = \mathbb{1}_K^\infty$ , then  $\varphi^\circ = \mathbb{1}_{K^\circ}^\infty$  and

$$e^{-\varphi} = \mathbb{1}_K \implies e^{-\varphi^\circ} = \mathbb{1}_{K^\circ}.$$

The polar transform plays an essential role in functional analogues of the Blaschke–Santaló inequality. We refer to [6, Chapter 9] for more information and references.

We shall work with the scaled version

$$\varphi_{\mathcal{A}}(x) = (50n)^2 \varphi^\circ(x/n)$$

and define the polar log-concave function of  $f = \exp(-\varphi)$  by

$$f_{\mathcal{A}}(x) = \exp(-\varphi_{\mathcal{A}}(x)).$$

We would like to mention here that Gilboa, Segal and Slomka [18] have also used some scaled version of the polarity transform to study the Mahler product of geometric log-concave functions. More precisely, they showed that if  $q \approx n^2$  then

$$\left( \int_{\mathbb{R}^n} e^{-\varphi(x)} dx \right)^{1/n} \left( \int_{\mathbb{R}^n} e^{-q\mathcal{A}\varphi(x)} dx \right)^{1/n} \approx \frac{1}{n}$$

for every centered geometric log-concave function  $f = e^{-\varphi}$  with finite positive integral. They also obtained an analogous result for the  $\mathcal{J}$ -transform, defined as  $\mathcal{J} = \mathcal{L}\mathcal{A} = \mathcal{A}\mathcal{L}$ .

**2.3. Isotropic geometric log-concave functions.** Let  $f : \mathbb{R}^n \rightarrow [0, \infty)$  be a log-concave function with finite positive integral. The barycenter of  $f$  is defined by

$$\text{bar}(f) = \frac{\int_{\mathbb{R}^n} x f(x) dx}{\int_{\mathbb{R}^n} f(x) dx},$$

and its isotropic constant is the affine-invariant quantity

$$(2.1) \quad L_f := \left( \frac{\|f\|_\infty}{\int_{\mathbb{R}^n} f(x) dx} \right)^{1/n} \det(\text{Cov}(f))^{1/(2n)},$$

where

$$\text{Cov}(f) := \frac{1}{\int_{\mathbb{R}^n} f(x) dx} \int_{\mathbb{R}^n} x \otimes x f(x) dx - \text{bar}(f) \otimes \text{bar}(f)$$

is the covariance matrix of  $f$ . A log-concave function  $f$  is called isotropic if

$$\text{bar}(f) = 0 \quad \int_{\mathbb{R}^n} f(x) dx = 1 \quad \text{and} \quad \text{Cov}(f) = \lambda_f^2 I_n$$

for some  $\lambda_f > 0$ .

A convex body  $K$  in  $\mathbb{R}^n$  is called isotropic if  $\text{vol}_n(K) = 1$ ,  $\text{bar}(K) = 0$ , and  $\text{Cov}(\mu_K) = L_{\mu_K}^2 I_n$ , where  $\mu_K$  is the uniform measure on  $K$ . Note that  $K$  is isotropic if and only if its indicator function  $\mathbb{1}_K$  is isotropic.

It is straightforward to check that any centered log-concave function  $f$  admits an invertible linear map  $T \in GL_n$  such that  $f_1 := f \circ T$  is isotropic; moreover,  $L_{f_1} = L_f$ . Since  $f_1(0) = \|f_1\|_\infty$ , dividing  $f_1$  by  $f_1(0)$  yields a function in  $LC_g(\mathbb{R}^n)$ . From (2.1) we obtain

$$\int_{\mathbb{R}^n} f_1(x) dx = a^n, \quad a := \lambda_{f_1}/L_f.$$

Define  $f_2(x) := f_1(ax)$ . Then

$$f_2(0) = \|f_2\|_\infty = 1, \quad \int_{\mathbb{R}^n} f_2(x) dx = 1, \quad \text{Cov}(f_2) = L_f^2 I_n.$$

A log-concave function satisfying these properties is called an isotropic geometric log-concave function. Thus every centered log-concave  $f$  with finite positive integral admits an isotropic position  $\tilde{f} = f \circ T$  for some  $T \in GL_n$ .

Bourgain's slicing problem [10] asked if there exists an absolute constant  $C > 0$  such that

$$(2.2) \quad L_n := \max\{L_K : K \text{ is an isotropic convex body in } \mathbb{R}^n\} \leq C.$$

K. Ball [7] proved that for every  $n$ ,

$$\sup_f L_f \leq C_1 L_n,$$

where the supremum is taken over isotropic log-concave functions  $f$  on  $\mathbb{R}^n$ . Bourgain [11] showed that  $L_n \leq cn^{1/4} \ln n$ , improved by Klartag [20] to  $L_n \leq cn^{1/4}$ . These were the best known bounds until 2020. In a breakthrough, Chen [13] proved that for every  $\epsilon > 0$ ,

$$L_n \leq n^\epsilon \quad \text{for all sufficiently large } n.$$

This initiated a series of developments culminating in the complete resolution of Bourgain's problem by Klartag and Lehec [21], who proved that  $L_n \leq C$ , building on an important contribution of Guan [19]. Shortly thereafter, Bizeul [8] provided an alternative proof.

**2.4. Covering numbers of isotropic convex bodies.** Let  $K$  be a convex body in  $\mathbb{R}^n$  with  $0 \in \text{int}(K)$ . Define its Minkowski functional  $\|x\|_K := \inf\{t > 0 : x \in tK\}$  and its support function  $h_K(x) := \max\{\langle x, y \rangle : y \in K\}$ . Set

$$M(K) := \int_{S^{n-1}} \|x\|_K d\sigma(x), \quad M^*(K) := \int_{S^{n-1}} h_K(x) d\sigma(x),$$

where  $\sigma$  is the rotationally invariant probability measure on  $S^{n-1}$ .

When  $K$  is symmetric, the classical Sudakov and dual Sudakov inequalities [5, Chapter 4] provide upper bounds on covering numbers in terms of  $M(K)$  and  $M^*(K)$ :

$$(2.3) \quad N(K, tB_2^n) \leq \exp\left(cn \frac{M^*(K)^2}{t^2}\right), \quad N(B_2^n, tK) \leq \exp\left(cn \frac{M(K)^2}{t^2}\right),$$

for every  $t > 0$ , where  $c > 0$  is an absolute constant.

E. Milman [22] proved that if  $K$  is isotropic then

$$(2.4) \quad M^*(K) \leq C\sqrt{n}(\ln n)^2 L_K \leq c_1\sqrt{n}(\ln n)^2,$$

the second inequality following from the boundedness of  $L_n$ . This dependence on  $n$  is optimal up to logarithmic factors.

The dual estimate was recently obtained by Bizeul and Klartag [9]:

$$(2.5) \quad M(K) \leq c_2 \frac{\log n}{\sqrt{n}}.$$

Let  $r_K$  denote the radius of the Euclidean ball with the same volume as  $K$ , i.e.  $\text{vol}_n(K) = \text{vol}_n(r_K B_2^n)$ . For isotropic bodies we have  $\text{vol}_n(K) = 1$  and hence this radius depends only on the dimension:  $r_K = r_n = \omega_n^{-1/n}$ , and  $r_n \simeq \sqrt{n}$ .

Combining the bounds (2.4) and (2.5) with (2.3), the second named author [28] showed that every isotropic convex body is essentially in a 2-regular  $M$ -position.

**Proposition 2.1.** *Let  $K$  be an isotropic convex body in  $\mathbb{R}^n$ . Then for every  $t \geq 1$ ,*

$$(2.6) \quad \max\{N(K, tr_n B_2^n), N(B_2^n, tr_n K^\circ)\} \leq \exp\left(\frac{\gamma_n^2 n}{t^2}\right),$$

$$(2.7) \quad \max\{N(r_n B_2^n, tK), N(r_n K^\circ, tB_2^n)\} \leq \exp\left(\frac{\delta_n^2 n}{t^2}\right),$$

where  $\gamma_n \leq c_1(\ln n)^2$  and  $\delta_n \leq c_2 \ln n$ .

These estimates provide a quantitative control of covering numbers for isotropic bodies and their polars, which is crucial in applications. In particular, they will play an essential role in the proof of Theorem 1.3.

**2.5. Functional covering numbers.** Recall that for any pair of functions  $f, g \in LC_g(\mathbb{R}^n)$ , the covering number of  $f$  by  $g$  is defined by

$$N(f, g) = \inf\{\mu(\mathbb{R}^n) : \mu * g \geq f\},$$

where the infimum is taken over all non-negative Borel measures  $\mu$  on  $\mathbb{R}^n$  satisfying

$$\int g(x - t) d\mu(t) \geq f(x), \quad x \in \mathbb{R}^n.$$

Intuitively,  $N(f, g)$  measures the minimal “weight” of translates of  $g$  needed to dominate  $f$ . This generalizes the classical notion of covering numbers for convex bodies: it is useful to note that if  $K$  and  $T$  are convex bodies in  $\mathbb{R}^n$ , then

$$(2.8) \quad N(\mathbb{1}_K, \mathbb{1}_T) \leq N(K, T).$$

For the proof of (2.8), let  $N = N(K, T)$  and choose points  $x_1, \dots, x_N \in \mathbb{R}^n$  such that  $K \subseteq \bigcup_{j=1}^N (x_j + T)$ . Let  $\mu$  be the counting measure on  $\{x_1, \dots, x_N\}$ . Then

$$\int_{\mathbb{R}^n} \mathbb{1}_T(x - t) d\mu(t) = \sum_{j=1}^N \mathbb{1}_T(x - x_j) = \sum_{j=1}^N \mathbb{1}_{x_j + T}(x) \geq \mathbb{1}_{\bigcup_{j=1}^N (x_j + T)}(x) \geq \mathbb{1}_K(x),$$

which shows that  $\mu * \mathbb{1}_T \geq \mathbb{1}_K$ , and  $\mu(\mathbb{R}^n) = N$ . Thus  $N(\mathbb{1}_K, \mathbb{1}_T) \leq N(K, T)$ .

Functional covering numbers satisfy several properties analogous to classical covering numbers. In the next lemma we collect the ones that will be used later in the proof of Theorem 1.3. A detailed proof of these properties can be found in [4, Section 2], and they hold more generally for non-negative measurable functions.

**Lemma 2.2.** *Let  $f, g, h, w, f_i, g_i \in LC_g(\mathbb{R}^n)$ . Then, for any  $a, b > 0$  and  $T \in GL_n$ ,*

- (i)  $N(af, bg) = \frac{a}{b} N(f, g)$ .
- (ii)  $N(f \circ T, g \circ T) = N(f, g)$ .
- (iii)  $N(f_1 + f_2, g) \leq N(f_1, g) + N(f_2, g)$ .
- (iv) *If  $f_1 \leq f_2$  and  $g_1 \geq g_2$ , then  $N(f_1, g_1) \leq N(f_2, g_2)$ .*
- (v)  $N(f, g) \leq N(f, h) N(h, g)$ .

Artstein-Avidan and Slomka [4] also defined the separation number of  $f$  by  $g$ :

$$M(f, g) = \sup \left\{ \int f d\rho : \rho * g \leq 1 \right\},$$

where the supremum is over all non-negative Borel measures  $\rho$  on  $\mathbb{R}^n$  that satisfy

$$\int g(x - t) d\rho(t) \leq 1 \quad \text{for all } x \in \mathbb{R}^n.$$

Any such measure  $\rho$  is called a separation measure of  $g$ . Recall that the separation number  $M(K, T)$  of two convex bodies  $K$  and  $T$  in  $\mathbb{R}^n$  is the maximal cardinality of a  $T$ -separated subset of  $K$ , i.e.

$$M(K, T) = \max \left\{ M \in \mathbb{N} : \exists x_1, \dots, x_M \in K \text{ such that } (x_i + T) \cap (x_j + T) = \emptyset \forall i \neq j \right\}.$$

It is useful to note that

$$(2.9) \quad M(K, T) \leq M(\mathbb{1}_K, \mathbb{1}_T).$$

For the proof of (2.9), let  $M = M(K, T)$  and choose  $x_1, \dots, x_M \in K$  such that  $(x_i + T) \cap (x_j + T) = \emptyset$  for all  $1 \leq i \neq j \leq M$ . Let  $\mu$  be the counting measure on  $\{x_1, \dots, x_M\}$ . Then

$$\int_{\mathbb{R}^n} \mathbb{1}_T(x - t) d\mu(t) = \sum_{j=1}^M \mathbb{1}_{x_j + T}(x) = \mathbb{1}_{\cup_{j=1}^M (x_j + T)}(x) \leq 1,$$

which shows that  $\mu * \mathbb{1}_T \leq 1$ , and  $\mu(\mathbb{R}^n) = M$ . Thus  $M(K, T) \leq M(\mathbb{1}_K, \mathbb{1}_T)$ .

A remarkable result of Artstein-Avidan and Slomka [4] shows that for log-concave functions, the notions of covering and separation essentially coincide (up to reflection):

**Theorem 2.3** (Artstein–Slomka). *Let  $f, g \in LC_g(\mathbb{R}^n)$ . Then,  $M(f, \bar{g}) = N(f, g)$ , where  $\bar{g}(x) = g(-x)$ .*

In the same work, Artstein-Avidan and Slomka obtained the following general bounds. If  $f, g$  are geometric log-concave functions, then

$$\frac{\int f^2(x) dx}{\|f * \bar{g}\|_\infty} \leq N(f, g) \leq 2^n \frac{\int f^2(x) dx}{\|f * g\|_\infty}.$$

If, in addition,  $f$  and  $g$  are even functions, then

$$\frac{\int f^2(x) dx}{\int f(x)g(x) dx} \leq N(f, g) \leq 2^n \frac{\int f^2(x) dx}{\int f(x)g(x) dx}.$$

Moreover, for every  $p > 1$ ,

$$\frac{\int f(x) dx}{\int g(x) dx} \leq N(f, g) \leq \frac{\int (f \star \bar{g}^{p-1})(x) dx}{\int \bar{g}^p(x) dx}.$$

Using these inequalities, Artstein-Avidan and Slomka showed in [4] that if  $f, g \in LC_g(\mathbb{R}^n)$  are centered, then

$$C^{-n}N(g^*, f^*) \leq N(f, g) \leq C^n N(g^*, f^*).$$

where  $C > 0$  is an absolute constant. Later, Gilboa, Segal, and Slomka proved in [18] that if  $q \approx n^2$  and  $\varphi, \psi$  are convex geometric functions such that either  $\text{bar}(\varphi) = 0$  or  $\text{bar}(\mathcal{A}\varphi) = 0$ , and likewise either  $\text{bar}(\psi) = 0$  or  $\text{bar}(\mathcal{A}\psi) = 0$ , then

$$C^{-n}N(e^{-q\mathcal{A}\psi}, e^{-q\mathcal{A}\phi}) \leq N(e^{-\varphi}, e^{-\psi}) \leq C^n N(e^{-q\mathcal{A}\psi}, e^{-q\mathcal{A}\phi}).$$

These results may be viewed as functional analogues of the well-known inequality

$$C^{-n}N(T^\circ, K^\circ) \leq N(K, T) \leq C^n N(T^\circ, K^\circ)$$

due to König and Milman (see [5, Theorem 8.2.3]), which holds for every pair of symmetric convex bodies  $K$  and  $T$  in  $\mathbb{R}^n$ .

### 3 Regular functional covering numbers

In this section we prove that every centered geometric log-concave function admits a regular covering  $M$ -position. Our approach relies on the existence of an almost 2-regular  $M$ -position for convex bodies (Proposition 2.1). In fact, in Theorem 1.3 we show that every isotropic geometric log-concave function is in an almost 1-regular  $M$ -position.

Let  $f : \mathbb{R}^n \rightarrow [0, \infty)$  be a centered log-concave function with  $f(0) > 0$ . We associate to  $f$  two classical families of convex bodies, denoted by  $\{R_t(f)\}_{t \geq 1}$  and  $\{K_t(f)\}_{t \geq 1}$ . First, for every  $t \geq 1$ , define

$$R_t(f) = \{x \in \mathbb{R}^n : f(x) \geq e^{-t} f(0)\}.$$

Since  $f$  is log-concave, the sets  $R_t(f)$  are convex, and clearly  $0 \in \text{int}(R_t(f))$ . To show that  $R_t(f)$  is bounded, recall that every log-concave function with finite positive integral satisfies (see [12, Lemma 2.2.1]) the estimate

$$(3.1) \quad f(x) \leq A e^{-B|x|} \quad \text{for all } x \in \mathbb{R}^n,$$

for some constants  $A, B > 0$ . Thus, if  $x \in R_t(f)$  then

$$|x| \leq \frac{1}{B} (\ln(A/f(0)) + t).$$

The second family of convex bodies  $K_t(f)$  was introduced by K. Ball, who also proved their convexity in [7]. For every  $t \geq 1$ , define

$$K_t(f) = \left\{ x \in \mathbb{R}^n : \int_0^\infty r^{t-1} f(rx) dr \geq \frac{f(0)}{t} \right\}.$$

Its radial function is given by

$$(3.2) \quad \varrho_{K_t(f)}(x) = \left( \frac{1}{f(0)} \int_0^\infty t r^{t-1} f(rx) dr \right)^{1/t}, \quad x \neq 0.$$

For  $0 < t \leq s$  one has the inclusions (see [12, Prop. 2.5.7])

$$(3.3) \quad \frac{\Gamma(t+1)^{1/t}}{\Gamma(s+1)^{1/s}} K_s(f) \subseteq K_t(f) \subseteq \left( \frac{\|f\|_\infty}{f(0)} \right)^{\frac{1}{t}-\frac{1}{s}} K_s(f).$$

Moreover, since  $f$  is assumed centered and log-concave, we have that  $\|f\|_\infty/f(0) \leq e^n$ ; this inequality is due to Fradelizi [14].

The next relation between the bodies  $K_t(f)$  and  $R_t(f)$  follows directly from the definitions (see [16, Proposition 2.3]).

**Proposition 3.1.** *Let  $f : \mathbb{R}^n \rightarrow [0, \infty)$  be a centered log-concave function with  $f(0) > 0$ . For every  $s \geq t$  we have*

$$R_t(f) \subseteq e^{t/s} K_s(f).$$

In the opposite direction we use the following estimate (see [16, Proposition 2.4]).

**Proposition 3.2.** *Let  $f : \mathbb{R}^n \rightarrow [0, \infty)$  be a centered log-concave function with  $f(0) > 0$ . For every  $t \geq 2n$ ,*

$$R_{5t}(f) \supseteq \left(1 - \frac{2n}{t}\right) K_t(f).$$

*If in addition  $f$  is even, then*

$$R_{5t}(f) \supseteq (1 - e^{-t}) K_t(f).$$

We now introduce the convex body

$$R_f := R_{50n}(f).$$

**Lemma 3.3.** *Let  $f : \mathbb{R}^n \rightarrow [0, \infty)$  be a centered log-concave function with  $f(0) > 0$ . There exists a centered convex body  $K \subset \mathbb{R}^n$  such that*

$$d_G(R_f, K) \leq C,$$

*where  $C > 0$  is an absolute constant. In fact, we may choose  $K = K_{n+1}(f)$ .*

*Proof.* Using Proposition 3.1 and (3.3) we obtain

$$(3.4) \quad R_f = R_{50n}(f) \subseteq e K_{50n}(f) \subseteq \alpha_1 K_{n+1}(f),$$

for some absolute constant  $\alpha_1 > 0$ . Using Proposition 3.2 and (3.3), and taking into account Fradelizi's inequality,

$$(3.5) \quad \frac{4}{5e} K_{n+1}(f) \subseteq \frac{4}{5} K_{10n}(f) = \left(1 - \frac{2n}{10n}\right) K_{10n}(f) \subseteq R_{50n}(f) = R_f.$$

Thus,

$$(3.6) \quad \alpha_2 K_{n+1}(f) \subseteq R_f \subseteq \alpha_1 K_{n+1}(f), \quad \alpha_2 = \frac{4}{5e}.$$

Since  $K_{n+1}(f)$  is centered (see [12, Proposition 2.5.3]), the lemma is proved.  $\square$

In what follows, we also set

$$(3.7) \quad r_f = (\text{vol}_n(R_f)) / \omega_n)^{1/n}.$$

We need three intermediate results.

**Proposition 3.4.** *Let  $f : \mathbb{R}^n \rightarrow [0, \infty)$  be a geometric log-concave function. If  $\text{vol}_n(R_f)^{1/n} \approx 1$  and  $R_f$  satisfies*

$$(3.8) \quad \max\left\{N(R_f, \text{tr}_f B_2^n), N(B_2^n, \text{tr}_f(R_f)^\circ)\right\} \leq \exp\left(\frac{c_1 \gamma_n^2 n}{t^2}\right),$$

*for some  $\gamma_n \geq 1$  and every  $t \geq 1$ , then*

$$N(f, t \odot g) \leq \exp\left(\frac{\gamma_n^2 n}{t}\right) \quad \text{for all } t \geq 1.$$

*Proof.* We first claim that

$$(3.9) \quad f(x) \leq \mathbb{1}_{R_f}(x) + \exp(-50n \|x\|_{R_f}), \quad x \in \mathbb{R}^n.$$

If  $x \in R_f$ , then  $f(x) \leq 1 = \mathbb{1}_{R_f}(x)$ . If  $x \notin R_f$ , then  $\|x\|_{R_f} > 1$  and by definition  $f(x/\|x\|_{R_f}) = \exp(-50n)$ . Log-concavity yields

$$f(x) \leq \exp(-50n \|x\|_{R_f}).$$

Next, decompose  $\exp(-50n\|x\|_{R_f})$  as

$$(3.10) \quad \exp(-50n\|x\|_{R_f}) = \sum_{k=0}^{\infty} e^{-50n\|x\|_{R_f}} \mathbb{1}_{\{k \leq 50n\|x\|_{R_f} < k+1\}}(x) \leq \sum_{k=0}^{\infty} e^{-k} \mathbb{1}_{\frac{k+1}{50n} R_f}(x).$$

Combining (3.9), (3.10), and Lemma 2.2 (iii),

$$(3.11) \quad N(f, t \odot g) \leq N(\mathbb{1}_{R_f}, t \odot g) + \sum_{k=0}^{\infty} e^{-k} N(\mathbb{1}_{\frac{k+1}{50n} R_f}, t \odot g).$$

We begin with  $N(\mathbb{1}_{R_f}, t \odot g)$ . By submultiplicativity,

$$(3.12) \quad N(\mathbb{1}_{R_f}, t \odot g) \leq N(\mathbb{1}_{R_f}, \mathbb{1}_{\sqrt{tr_f} B_2^n}) N(\mathbb{1}_{\sqrt{tr_f} B_2^n}, t \odot g).$$

By (2.8) and (3.8),

$$(3.13) \quad N(\mathbb{1}_{R_f}, \mathbb{1}_{\sqrt{tr_f} B_2^n}) \leq \exp\left(\frac{c\gamma_n^2 n}{t}\right).$$

Since  $\text{vol}(R_f)^{1/n} \approx 1$ , we have  $r_f \approx \sqrt{n}$ , and for  $x \in \sqrt{tr_f} B_2^n$ ,

$$\exp\left(-\frac{|x|^2}{2t^2}\right) \geq \exp\left(-\frac{r_f^2}{2t}\right) \geq \exp(-cn/t),$$

where  $c > 0$  is an absolute constant. Thus

$$\mathbb{1}_{\sqrt{tr_f} B_2^n}(x) \leq e^{cn/t} (t \odot g)(x),$$

and hence (by Lemma 2.2 (i))

$$(3.14) \quad N(\mathbb{1}_{\sqrt{tr_f} B_2^n}, t \odot g) \leq e^{cn/t}.$$

Combining (3.13)–(3.14) gives

$$(3.15) \quad N(\mathbb{1}_{R_f}, t \odot g) \leq \exp\left(\frac{c_1 \gamma_n^2 n}{t}\right).$$

Next, we give an upper bound for the sum in (3.11). For  $k \geq 0$ , using (3.14) and submultiplicativity, we write

$$\begin{aligned} N(\mathbb{1}_{\frac{k+1}{50n} R_f}, t \odot g) &\leq N(\mathbb{1}_{\frac{k+1}{50n} R_f}, \mathbb{1}_{\sqrt{tr_f} B_2^n}) N(\mathbb{1}_{\sqrt{tr_f} B_2^n}, t \odot g) \\ &\leq e^{cn/t} N(R_f, \sqrt{tr_f} B_2^n) N(B_2^n, \frac{50n}{k+1} B_2^n). \end{aligned}$$

Using (3.8) and the bound  $N(B_2^n, \lambda B_2^n) \leq (1 + 2/\lambda)^n$ ,

$$N(\mathbb{1}_{\frac{k+1}{50n} R_f}, t \odot g) \leq \exp\left(\frac{c_2 \gamma_n^2 n}{t}\right) e^{\frac{k+1}{25}}.$$

It follows that

$$\sum_{k=0}^{\infty} e^{-k} N(\mathbb{1}_{\frac{k+1}{50n} R_f}, t \odot g) \leq C_1 \exp\left(\frac{c_2 \gamma_n^2 n}{t}\right),$$

and together with (3.11) and (3.15),

$$N(f, t \odot g) \leq \exp\left(\frac{c_1 \gamma_n^2 n}{t}\right) + C_1 \exp\left(\frac{c_2 \gamma_n^2 n}{t}\right),$$

which gives the required bound.  $\square$

**Proposition 3.5.** *Let  $f : \mathbb{R}^n \rightarrow [0, \infty)$  be a geometric log-concave function. If  $\text{vol}_n(R_f)^{1/n} \approx 1$  and  $R_f$  satisfies*

$$(3.16) \quad \max\left\{N(r_f B_2^n, t R_f), N(r_f R_f^\circ, t B_2^n)\right\} \leq \exp\left(\frac{c_1 \delta_n^2 n}{t^2}\right)$$

for some  $\delta_n \geq 1$  and every  $t \geq 1$ , then

$$N(g, t \odot f) \leq \exp\left(\frac{\delta_n^2 n}{t}\right) \quad \text{for all } t \geq 1.$$

*Proof.* Let  $t \geq 1$ . If  $x \in R_f$ , then by definition  $f(x) \geq \exp(-50n)$ , and log-concavity gives

$$f(x/t) \geq f(x)^{1/t} \geq \exp(-50n/t).$$

Hence

$$\exp(-50n/t) \mathbb{1}_{R_f}(x) \leq (t \odot f)(x),$$

and Lemma 2.2(i) yields

$$(3.17) \quad N(g, t \odot f) \leq e^{-50n/t} N(g, \mathbb{1}_{R_f}).$$

Next decompose  $g$  into spherical annuli:

$$g(x) = \sum_{k=0}^{\infty} g(x) \mathbb{1}_{\{a k r_f \leq |x| < a(k+1)r_f\}}(x) \leq \sum_{k=0}^{\infty} e^{-a^2 k^2 r_f^2 / 2} \mathbb{1}_{a(k+1)r_f B_2^n}(x),$$

for some  $a > 0$  to be determined. By Lemma 2.2(iii),

$$(3.18) \quad N(g, \mathbb{1}_{R_f}) \leq \sum_{k=0}^{\infty} e^{-a^2 k^2 r_f^2 / 2} N(\mathbb{1}_{a(k+1)r_f B_2^n}, \mathbb{1}_{R_f}).$$

For each  $k \geq 0$ ,

$$(3.19) \quad \begin{aligned} N(\mathbb{1}_{a(k+1)r_f B_2^n}, \mathbb{1}_{R_f}) &\leq N(a(k+1)r_f B_2^n, R_f) \\ &\leq N\left(a(k+1)r_f B_2^n, \frac{1}{\sqrt{t}} r_f B_2^n\right) N(r_f B_2^n, \sqrt{t} R_f). \end{aligned}$$

Volumetric covering bounds give

$$N\left(a(k+1)r_f B_2^n, \frac{1}{\sqrt{t}} r_f B_2^n\right) \leq (2\sqrt{t} a(k+1) + 1)^n,$$

and by (3.16),

$$N(r_f B_2^n, \sqrt{t} R_f) \leq \exp\left(\frac{c_1 \delta_n^2 n}{t}\right).$$

Inserting the above into (3.19) we conclude that

$$N(\mathbb{1}_{a(k+1)r_f B_2^n}, \mathbb{1}_{R_f}) \leq (2\sqrt{t}a(k+1) + 1)^n \exp\left(\frac{c\delta_n^2 n}{t}\right),$$

Recall that  $\text{vol}_n(R_f)^{1/n} \approx 1$ , which implies  $r_f \approx \sqrt{n}$ . Substituting into (3.18) gives

$$N(g, \mathbb{1}_{R_f}) \leq \exp\left(\frac{c\delta_n^2 n}{t}\right) \sum_{k=0}^{\infty} (e^{-c_0 a^2 k^2 + 2\sqrt{t}a(k+1)})^n.$$

Choosing  $a = c_2 \sqrt{t}$  (for an absolute constant  $c_2 > 0$  sufficiently large) makes the series bounded by an absolute constant. Hence

$$N(g, \mathbb{1}_{R_f}) \leq C \exp\left(\frac{c\delta_n^2 n}{t}\right).$$

Inserting into (3.17) yields the desired estimate.  $\square$

**Proposition 3.6.** *Let  $f : \mathbb{R}^n \rightarrow [0, \infty)$  be a centered geometric log-concave function such that  $\text{vol}_n(R_f)^{1/n} \approx 1$  and  $R_f$  satisfies*

$$(3.20) \quad N((R_f)^\circ, t r^\circ B_2^n) \leq \exp\left(\frac{\delta_n^2 n}{t^2}\right) \quad \text{and} \quad N(r^\circ B_2^n, (R_f)^\circ) \leq \exp\left(\frac{\gamma_n^2 n}{t^2}\right)$$

for some  $\gamma_n, \delta_n \geq 1$  and every  $t \geq 1$ , where  $r^\circ B_2^n$  is the Euclidean ball having the same volume as  $(R_f)^\circ$ . Define

$$R_{f^*} := \{x \in \mathbb{R}^n : f^*(x) \geq e^{-50n}\},$$

where  $f^*$  is the Legendre dual of  $f$ . Then  $\text{vol}_n(R_{f^*})^{1/n} \approx 1$  and  $R_{f^*}$  satisfies

$$(3.21) \quad N(R_{f^*}, t r^* B_2^n) \leq \exp\left(\frac{c\delta_n^2 n}{t^2}\right) \quad \text{and} \quad N(r^* B_2^n, t R_{f^*}) \leq \exp\left(\frac{c\gamma_n^2 n}{t^2}\right)$$

for every  $t \geq 1$ , where  $r^* B_2^n$  is the ball having the same volume as  $R_{f^*}$  and  $c > 0$  is an absolute constant.

*Proof.* Write  $f = e^{-\varphi}$ , where  $\varphi$  is convex. Then  $f^* = e^{-\mathcal{L}\varphi}$ , where  $\mathcal{L}\varphi$  is the Legendre transform. By [15, Lemma 8], for all  $s, t > 0$ ,

$$(3.22) \quad t\{x : \varphi(x) \leq t\}^\circ \subset \{y : \mathcal{L}\varphi(y) \leq t\} \subset (t+s)\{x : \varphi(x) \leq s\}^\circ.$$

Setting  $s = t = 50n$  in (3.22) gives

$$(3.23) \quad 50n (R_f)^\circ \subseteq R_{f^*} \subseteq 100n (R_f)^\circ,$$

which implies

$$50n r^\circ \leq r^* \leq 100n r^\circ.$$

Using (3.20) for  $(R_f)^\circ$ , we obtain

$$N(R_{f^*}, t r^* B_2^n) \leq N(100n (R_f)^\circ, 50nt r^\circ B_2^n) \leq \exp\left(\frac{c\gamma_n^2 n}{t^2}\right),$$

and similarly,

$$N(r^* B_2^n, t R_{f^*}) \leq N(100n r^\circ B_2^n, 50nt (R_f)^\circ) \leq \exp\left(\frac{c\delta_n^2 n}{t^2}\right).$$

From Lemma 3.3 we know that  $R_f$  has bounded geometric distance from a centered convex body. Therefore, we may apply the Blaschke-Santaló and Bourgain-Milman inequalities (up to an absolute constant) to  $R_f$ . Combining with (3.23) yields

$$\text{vol}_n(R_{f^*})^{1/n} \approx n \text{vol}_n((R_f)^\circ)^{1/n} \approx 1 / \text{vol}_n(R_f)^{-1/n} \approx 1,$$

completing the proof.  $\square$

We are now ready for the proof of the main theorem.

*Proof of Theorem 1.3.* Let  $f : \mathbb{R}^n \rightarrow [0, \infty)$  be an isotropic geometric log-concave function. Then

$$f(0) = \|f\|_\infty = 1, \quad \int_{\mathbb{R}^n} f(x) dx = 1.$$

The convex body  $K_{n+1}(f)$  is isotropic, and therefore, by Proposition 2.1,

$$(3.24) \quad \max\{N(K_{n+1}(f), tr_n B_2^n), N(B_2^n, tr_n(K_{n+1}(f))^\circ)\} \leq \exp\left(\frac{\gamma_n^2 n}{t^2}\right),$$

$$(3.25) \quad \max\{N(r_n B_2^n, tK_{n+1}(f)), N(r_n(K_{n+1}(f))^\circ, tB_2^n)\} \leq \exp\left(\frac{\delta_n^2 n}{t^2}\right),$$

for all  $t \geq 1$ , where  $\gamma_n \leq c(\ln n)^2$  and  $\delta_n \leq c \ln n$ .

Combining (3.6) with (3.24) and (3.25), we deduce that  $R_f$  satisfies (3.8) and (3.16). Moreover,

$$\text{vol}_n(R_f)^{1/n} \approx \text{vol}_n(K_{n+1}(f))^{1/n} = 1.$$

Applying Propositions 3.4 and 3.5, we obtain

$$N(f, t \odot g) \leq \exp\left(\frac{c\gamma_n^2 n}{t}\right) \quad \text{and} \quad N(g, t \odot f) \leq \exp\left(\frac{c\delta_n^2 n}{t}\right) \quad \text{for all } t \geq 1.$$

Next, Proposition 3.6 shows that  $R_{f^*}$  satisfies (3.20), and moreover

$$\text{vol}_n(R_{f^*})^{1/n} \approx 1.$$

Applying Propositions 3.4 and 3.5 to  $f^*$  yields

$$N(f^*, t \odot g) \leq \exp\left(\frac{c\delta_n^2 n}{t}\right) \quad \text{and} \quad N(g, t \odot f^*) \leq \exp\left(\frac{c\gamma_n^2 n}{t}\right) \quad \text{for all } t \geq 1.$$

This completes the proof. □

For the proof of Theorem 1.5 we shall use the next lemma from [24].

**Lemma 3.7.** *Let  $\varphi : \mathbb{R}^n \rightarrow [0, \infty)$  be a geometric convex function. For every  $t > 0$ ,*

$$(\{x : \varphi(x) < 1/t\})^\circ \subseteq \{x : \varphi^\circ(x) \leq t\} \subseteq 2(\{x : \varphi(x) < 1/t\})^\circ.$$

Consider the geometric log-concave function  $f = e^{-\varphi}$ . Applying Lemma 3.7 with  $t = \frac{1}{50n}$  we get

$$(3.26) \quad (R_f)^\circ \subseteq \{x : \varphi^\circ(x) \leq 1/(50n)\} \subseteq 2(R_f)^\circ.$$

We define the scaled polar  $\varphi_{\mathcal{A}}$  of  $\varphi$  by

$$\varphi_{\mathcal{A}}(x) = (50n)^2 \varphi^\circ(x/n).$$

Note that  $\varphi_{\mathcal{A}}(x) \leq 50n$  if and only if  $\varphi^\circ(x/n) \leq 1/(50n)$ . This shows that

$$(3.27) \quad n(R_f)^\circ \subseteq \{x : \varphi_{\mathcal{A}}(x) \leq 50n\} \subseteq 2n(R_f)^\circ,$$

and hence, if we define  $f_{\mathcal{A}} = e^{-\varphi_{\mathcal{A}}}$  we get

$$(3.28) \quad n(R_f)^\circ \subseteq R_{f_{\mathcal{A}}} \subseteq 2n(R_f)^\circ.$$

*Proof of Theorem 1.5.* We start as in the proof of Theorem 1.3. Recall that

$$\text{vol}_n(R_f)^{1/n} \approx \text{vol}_n(K_{n+1}(f))^{1/n} = 1$$

and  $R_f$  satisfies (3.8) and (3.16).

Combining (3.28) with the Blaschke-Santaló and Bourgain-Milman inequalities we get

$$\text{vol}_n(R_{f_A})^{1/n} \approx n \text{vol}_n((R_f)^\circ)^{1/n} \approx 1/\text{vol}_n(R_f)^{1/n} \approx 1.$$

In particular, if  $r_A$  denotes the radius of the ball that has volume  $\text{vol}_n(R_{f_A})$ , we see that  $r_A \approx \sqrt{n}$ .

Using (3.20) for  $(R_f)^\circ$ , we obtain

$$N(R_{f_A}, tr_A B_2^n) \leq N(2n(R_f)^\circ, tn r^\circ B_2^n) \leq \exp\left(\frac{c\gamma_n^2 n}{t^2}\right),$$

and similarly,

$$N(r_A B_2^n, tR_{f_A}) \leq N(2n r^\circ B_2^n, tn(R_f)^\circ) \leq \exp\left(\frac{c\gamma_n^2 n}{t^2}\right).$$

Since  $R_{f_A}$  satisfies (3.20), and moreover

$$\text{vol}_n(R_{f_A})^{1/n} \approx 1,$$

applying Propositions 3.4 and 3.5 to  $f_A$  yields

$$N(f_A, t \odot g) \leq \exp\left(\frac{c\delta_n^2 n}{t}\right) \quad \text{and} \quad N(g, t \odot f_A) \leq \exp\left(\frac{c\gamma_n^2 n}{t}\right) \quad \text{for all } t \geq 1.$$

This completes the proof.  $\square$

We now turn to the proofs of Theorems 1.4 and 1.6. We shall use the fact that if  $K$  is an isotropic convex body in  $\mathbb{R}^n$ , then

$$(3.29) \quad \max \{N(K, r_n B_2^n), N(r_n B_2^n, K), N(r_n K^\circ, B_2^n), N(B_2^n, r_n K^\circ)\} \leq C^n$$

for some absolute constant  $C > 0$ . This is a well-known consequence of the fact that  $L_n \leq C$ ; see, for example, [17, Theorem 3.3].

*Proof of Theorem 1.4.* We begin as in the proof of Theorem 1.3. Recall that  $K_{n+1}(f)$  is isotropic, and hence satisfies (3.29). Since  $R_f$  is at bounded geometric distance from  $K_{n+1}(f)$ , we obtain  $r_f \approx \sqrt{n}$ , or equivalently,

$$\text{vol}_n(R_f)^{1/n} \approx \text{vol}_n(K_{n+1}(f))^{1/n} = 1,$$

and  $R_f$  satisfies

$$(3.30) \quad \max \{N(R_f, r_f B_2^n), N(r_f B_2^n, R_f), N(r_n(R_f)^\circ, B_2^n), N(B_2^n, r_f(R_f)^\circ)\} \leq C^n$$

for some absolute constant  $C > 0$ . Following the proof of Proposition 3.4 with  $t = 1$  and (3.8) replaced by (3.30), we deduce that

$$(3.31) \quad N(f, g) \leq C_1^n$$

for some absolute constant  $C_1 > 0$ .

Similarly, applying the proof of Proposition 3.5 with  $t = 1$  and again replacing (3.8) by (3.30), we find

$$(3.32) \quad N(g, f) \leq C_2^n$$

for some absolute constant  $C_2 > 0$ .

Next, recall from the proof of Proposition 3.6 that

$$R_{f^*} \approx n(R_f)^\circ,$$

and hence  $r^* \approx n r^\circ$ , where  $r^*$  denotes the volume radius of  $R_{f^*}$ . In particular,  $\text{vol}_n(R_{f^*})^{1/n} \approx 1$ . Since  $(R_f)^\circ$  satisfies (3.30), it follows that

$$N(R_{f^*}, r^* B_2^n) \leq N(c_1 n (R_f)^\circ, c_2 n r^\circ B_2^n) \leq C_3^n,$$

and similarly,

$$N(r^* B_2^n, R_{f^*}) \leq N(c_2 n r^\circ B_2^n, c_1 n (R_f)^\circ) \leq C_4^n.$$

Repeating the proofs of (3.31) and (3.32) with  $f^*$  in place of  $f$  now yields

$$(3.33) \quad N(f^*, g) \leq C_5^n \quad \text{and} \quad N(g, f^*) \leq C_6^n.$$

This completes the proof. □

*Proof of Theorem 1.6.* We only need to prove that

$$(3.34) \quad N(f_{\mathcal{A}}, g) \leq C_7^n \quad \text{and} \quad N(g, f_{\mathcal{A}}) \leq C_8^n.$$

The proof is similar to the second part of the proof of Theorem 1.4, once we recall that

$$R_{f_{\mathcal{A}}} \approx n(R_f)^\circ$$

by (3.28). □
