Abstract

The efficient numerical solution of fractional differential equations has been recently tackled through the definition of Fractional HBVMs (FHBVMs), a class of Runge-Kutta type methods. Corresponding Matlab[®] codes have been also made available on the internet, proving to be very competitive w.r.t. existing ones. However, so far, FHBVMs have been given for solving systems of fractional differential equations with the same order of fractional derivative, whereas the numerical solution of multi-order problems (i.e., problems in which different orders of fractional derivatives occur) has not been handled, yet. Due to their relevance in applications, in this paper we propose an extension of FHBVMs for addressing fractional multi-order problems, providing full details for such an approach. A corresponding Matlab[®] code, handling the case of two different fractional orders, is also made available, proving very effective for numerically solving these problems.

Keywords: Fractional Differential Equations, FDEs, Caputo derivative, Fractional HBVMs, FHBVMs, fractional multi-order problems.

MSC: 34A08, 65R20, 65-04.

1 Introduction

The idea of extending the definition of derivatives to the case of a non-integer order of differentiation dates back to 1695, to the correspondence between Leibniz and de l'Hôpital [48], when the meaning of the derivative of order one half was discussed. Although its theoretical foundation is centuries old, the concept of fractional derivative has recently evolved from a purely mathematical curiosity into a vital tool for modeling across a variety of scientific fields (see, e.g., [31, 33, 41, 43, 45, 50, 51], to mention a few), due to its ability to encompass memory terms. In fact, unless the ODE case, the differential operator here considered is of a nonlocal nature [20, 48]. For this reason, the numerical solution of FDEs has been the subject of many researches in the last years, starting

from the pioneering work of Lubich [40], where fractional versions of linear multistep formulae are considered: we refer, e.g., to [21, 22, 24, 25, 27, 36, 47], to mention a few of them. More recently, the class of *Fractional HBVMs (FHBVMs)* [8] has been introduced for the efficient numerical solution of initial value problems of fractional differential equations (FDE-IVPs) in the Caputo form, with one fractional derivative. The basic steps leading to the definition of FHBVMs are the following ones:

- local expansion of the vector field along a suitable Jacobi polynomial basis, naturally induced by the problem at hand;
- discretization of the corresponding Fourier coefficients, by using a corresponding Gauss-Jacobi quadrature;
- solution of the generated discrete problems, defined on a suitable discrete mesh.

FHBVMs have been efficiently implemented in the two Matlab[©] codes:

- `fhbvm`, [9, 10] using either a graded or a uniform mesh (depending on the features of the problem at hand);
- `fhbvm2`, [11] possibly also using a mixed mesh (initially graded and subsequently uniform).

An extensive experimentation [12] has proved that the above codes are extremely competitive w.r.t. publicly available ones, based on different numerical methods, due to the fact that the implemented FHBVM methods can achieve, alike in the ODE case [1], a spectrally accurate solution.

Nevertheless, multi-order systems of equations, i.e., systems where different fractional orders appear, are of interest in a number of applications, including material science [52, 48]), population dynamics [4], epidemic modelling [18, 37], pharmacokinetics [55], and chaotic dynamics [5, 30, 38, 49]. In this respect, the extension of FHBVMs for such problems poses important challenges: their study is precisely the goal of this paper.

Consequently, we shall hereafter consider multi-order problems in the following general form, for $\alpha_i \in (\ell - 1, \ell)$, $i = 1 \dots, \nu$, $\ell \in \mathbb{N}$, $\ell \geq 1$:

$$\begin{aligned} y_i^{(\alpha_i)}(t) &= f_i(y(t)), & t \in [0, T], \\ y_i^{(\iota)}(0) &= y_{i0}^\iota \in \mathbb{R}^{m_i}, & \iota = 0, \dots, \ell - 1, \quad i = 1, \dots, \nu, \\ y &= (y_1^\top, \dots, y_\nu^\top)^\top \in \mathbb{R}^m, & m = \sum_{i=1}^{\nu} m_i. \end{aligned} \tag{1}$$

Here, for all $i = 1, \dots, \nu$, assuming $y_i \in A^\ell([0, T])$ (i.e., $y_i^{(\ell-1)}$ is absolutely continuous),

$$y_i^{(\alpha_i)}(t) := \frac{1}{\Gamma(\ell - \alpha_i)} \int_0^t (t - x)^{\ell - \alpha_i - 1} y_i^{(\ell)}(x) dx \tag{2}$$

is the Caputo derivative of y_i and, for the sake of brevity, in (1) we have omitted t as a formal argument of f_i . The approach described in the following sections reduces to the usual one defining FHBVMs, when the $\{\alpha_i\}$ are all equal (or, equivalently, $\nu = 1$), but differs significantly both in the methodology and the implementations strategies, when they are different from each other.

With this premise, the structure of the paper is as sketched below. At first, in Section 2 we explain the possible approaches for extending FHBVMs to handle problem (1). Later on, in Sections 3 and 4, we provide full details for the corresponding discretization procedure, emphasizing the major difference in the choice of the discrete abscissae and quadratures. The practical solution of the generated discrete problems is then detailed in Section 5. As a result, a new version of the code `fhbvm2` in [11], named `fhbvm2_2`, is given in Section 6, handling at the moment the case $\nu = 2$. This latter code is later used in the numerical tests reported in Section 7. At last, some conclusions are given in Section 8.

2 Fractional HBVMs (FHBVMs)

To begin with, we recall that, under suitable regularity assumptions on the vector fields f_i , the solution of problem (1) can be formally written (see, e.g., [23]) as:

$$\begin{aligned} y_i(t) &= \sum_{\iota=0}^{\ell-1} \frac{y_{i0}^\iota}{\iota!} t^\iota + \frac{1}{\Gamma(\alpha_i)} \int_0^t (t-x)^{\alpha_i-1} y_i^{(\alpha_i)}(x) dx \\ &= \sum_{\iota=0}^{\ell-1} \frac{y_{i0}^\iota}{\iota!} t^\iota + \frac{1}{\Gamma(\alpha_i)} \int_0^t (t-x)^{\alpha_i-1} f_i(y(x)) dx \\ &\equiv T_{i\ell}(t) + I^{\alpha_i} f_i(y(t)), \quad t \in [0, T], \quad i = 1, \dots, \nu, \end{aligned} \quad (3)$$

with y defined according to (1), and $I^{\alpha_i} f_i(y(t))$ the Riemann-Liouville integral corresponding to (2).

Let us now consider, for explanation purposes, the case where problem (1) is, at first, solved over the reference interval $[0, h]$. To this end, we use the families of Jacobi polynomials $\{P_j^i\}_{j \geq 0}$, $i = 1, \dots, \nu$, respectively orthonormal w.r.t. the weighting functions:

$$\omega_i(c) = \alpha_i(1-c)^{\alpha_i-1}, \quad c \in [0, 1], \quad \implies \quad \int_0^1 \omega_i(c) P_r^i(c) P_j^i(c) dc = \delta_{rj}, \quad r, j = 0, 1, \dots \quad (4)$$

Next, we expand each vector field f_i in (1) along the corresponding family of polynomials, thus obtaining the equivalent problem

$$y_i^{(\alpha_i)}(ch) = f_i(y(ch)) \equiv \sum_{j \geq 0} P_j^i(c) \gamma_{ij}(y), \quad c \in [0, 1], \quad (5)$$

$$y_i^{(\iota)}(0) = y_{i0}^\iota \in \mathbb{R}^{m_i}, \quad \iota = 0, \dots, \ell-1, \quad i = 1, \dots, \nu,$$

with the corresponding Fourier coefficients defined as

$$\gamma_{ij}(y) = \int_0^1 \omega_i(\tau) P_j^i(\tau) f_i(y(\tau h)) d\tau, \quad j = 0, 1, \dots \quad (6)$$

Integrating (5) side by side, and imposing the initial conditions, one then obtains

$$y_i(ch) = T_{i\ell}(ch) + h^{\alpha_i} \sum_{j \geq 0} I^{\alpha_i} P_j^i(c) \gamma_{ij}(y), \quad c \in [0, 1], \quad i = 1, \dots, \nu, \quad (7)$$

which is equivalent to (3), for $t \in [0, h]$. Moreover, by considering that

$$P_0^i(c) \equiv 1 \quad \text{and} \quad I^{\alpha_i} P_j^i(1) = \frac{\delta_{j0}}{\Gamma(\alpha_i + 1)},$$

from (4), (6), and (7) one derives:

$$\begin{aligned} y_i(h) &= T_{i\ell}(h) + \frac{h^{\alpha_i}}{\Gamma(\alpha_i + 1)} \gamma_{i0}(y) = T_{i\ell}(h) + \frac{h^{\alpha_i}}{\Gamma(\alpha_i) \alpha_i} \gamma_{i0}(y) \\ &= T_{i\ell}(h) + \frac{1}{\Gamma(\alpha_i)} \int_0^h (h-x)^{\alpha_i-1} f_i(y(x)) dx \\ &\equiv T_{i\ell}(h) + I^{\alpha_i} f_i(y(h)), \end{aligned} \quad (8)$$

that is, (3) at $t = h$. Polynomial approximations of degree $s-1$ to (5) are obtained by truncating the infinite series to finite sums with s terms:

$$\begin{aligned} \sigma_i^{(\alpha_i)}(ch) &= \sum_{j=0}^{s-1} P_j^i(c) \gamma_{ij}(\sigma), \quad c \in [0, 1], \\ \sigma_i^{(\iota)}(0) &= y_{i0}^\iota \in \mathbb{R}^{m_i}, \quad \iota = 0, \dots, \ell-1, \quad i = 1, \dots, \nu, \\ \sigma &= (\sigma_1^\top, \dots, \sigma_\nu^\top)^\top \in \mathbb{R}^m, \end{aligned} \quad (9)$$

with the Fourier coefficients $\gamma_{ij}(\sigma)$ defined according to (6), by formally replacing y with σ . As is clear, this is equivalent to requiring the residuals be orthogonal to all polynomials of degree $s-1$, w.r.t. the inner product defined by (4):¹

$$\int_0^1 \omega_i(c) P_j^i(c) \left[\sigma_i^{(\alpha_i)}(ch) - f_i(\sigma_i(ch)) \right] dc = 0, \quad j = 0, \dots, s-1, \quad i = 1, \dots, \nu. \quad (10)$$

Similarly to (7), the approximations σ_i are then given by integrating (9) side by side and imposing the initial conditions:

$$\begin{aligned} \sigma_i(ch) &= T_{i\ell}(ch) + \frac{h^{\alpha_i}}{\Gamma(\alpha_i)} \int_0^c (c-\tau)^{\alpha_i-1} \sigma_i^{(\alpha_i)}(\tau h) d\tau \equiv T_{i\ell}(ch) + I^{\alpha_i} \sigma_i^{(\alpha_i)}(ch) \\ &= T_{i\ell}(ch) + h^{\alpha_i} \sum_{j=0}^{s-1} I^{\alpha_i} P_j^i(c) \gamma_{ij}(\sigma), \quad c \in [0, 1], \quad i = 1, \dots, \nu. \end{aligned} \quad (11)$$

In particular, at $t = h$ one derives, similarly as in (8):

$$\begin{aligned} \sigma_i(h) &= T_{i\ell}(h) + \frac{h^{\alpha_i}}{\Gamma(\alpha_i + 1)} \gamma_{i0}(\sigma) \\ &= T_{i\ell}(h) + \frac{1}{\Gamma(\alpha_i)} \int_0^h (h-x)^{\alpha_i-1} f_i(\sigma(x)) dx \\ &\equiv T_{i\ell}(h) + I^{\alpha_i} f_i(\sigma(h)), \quad i = 1, \dots, \nu. \end{aligned}$$

¹This feature is common to HBVMs, obtained when $\alpha_i = 1$ [2, 13, 14].

Next, let us return to the interval $[0, T]$, and consider the case where a mesh

$$t_n = t_{n-1} + h_n, \quad n = 1, \dots, N, \quad t_0 = 0, \quad t_N = T, \quad (12)$$

is given. Consequently, now $\sigma(t)$ becomes a piecewise approximation to $y(t)$ on the whole interval. Moreover, let us denote:

$$\begin{aligned} \sigma_{in}(ch_n) &= \sigma_i(t_{n-1} + ch_n), \\ \sigma_{in}^{(\alpha_i)}(ch_n) &= \sum_{j=0}^{s-1} P_j^i(c) \gamma_{ij}(\sigma^n), \\ \gamma_{ij}(\sigma^n) &= \int_0^1 \omega_i(c) P_j^i(c) f_i(\sigma^n(ch_n)) dc, \quad j = 0, \dots, s-1, \\ T_{i\ell}^n(ch_n) &= T_{i\ell}(t_{n-1} + ch_n), \quad i = 1, \dots, \nu, \\ \sigma^n(ch_n) &= \sigma(t_{n-1} + ch_n), \quad c \in [0, 1], \quad n = 1, \dots, N. \end{aligned} \quad (13)$$

Consequently, for $t = t_{n-1} + ch_n \in [t_{n-1}, t_n]$, $c \in [0, 1]$, one has:

$$\begin{aligned} \sigma_i(t) &\equiv \sigma_{in}(ch_n) = T_{i\ell}(t) + \frac{1}{\Gamma(\alpha_i)} \int_0^t (t-x)^{\alpha_i-1} \sigma_i^{(\alpha_i)}(x) dx \\ &= T_{i\ell}(t_{n-1} + ch_n) + \frac{1}{\Gamma(\alpha_i)} \int_0^{t_{n-1}+ch_n} (t_{n-1} + ch_n - x)^{\alpha_i-1} \sigma_i^{(\alpha_i)}(x) dx \\ &= T_{i\ell}^n(ch_n) + \frac{1}{\Gamma(\alpha_i)} \left[\sum_{\mu=1}^{n-1} \int_{t_{\mu-1}}^{t_\mu} (t_{n-1} + ch_n - x)^{\alpha_i-1} \sigma_i^{(\alpha_i)}(x) dx \right. \\ &\quad \left. + \int_{t_{n-1}}^{t_{n-1}+ch_n} (t_{n-1} + ch_n - x)^{\alpha_i-1} \sigma_i^{(\alpha_i)}(x) dx \right] \\ &= T_{i\ell}^n(ch_n) + \left[\sum_{\mu=1}^{n-1} \frac{h_\mu^{\alpha_i}}{\Gamma(\alpha_i)} \int_0^1 \left(\frac{t_{n-1} + ch_n - t_{\mu-1}}{h_\mu} - \tau \right)^{\alpha_i-1} \sigma_{i\mu}^{(\alpha_i)}(\tau h_\mu) d\tau \right. \\ &\quad \left. + \frac{h_n^{\alpha_i}}{\Gamma(\alpha_i)} \int_0^c (c - \tau)^{\alpha_i-1} \sigma_{in}^{(\alpha_i)}(\tau h_n) d\tau \right] \\ &= T_{i\ell}^n(ch_n) + \left[\sum_{\mu=1}^{n-1} \frac{h_\mu^{\alpha_i}}{\Gamma(\alpha_i)} \int_0^1 \left(\frac{t_{n-1} + ch_n - t_{\mu-1}}{h_\mu} - \tau \right)^{\alpha_i-1} \sum_{j=0}^{s-1} P_j^i(\tau) \gamma_{ij}(\sigma^\mu) d\tau \right. \\ &\quad \left. + \frac{h_n^{\alpha_i}}{\Gamma(\alpha_i)} \int_0^c (c - \tau)^{\alpha_i-1} \sum_{j=0}^{s-1} P_j^i(\tau) \gamma_{ij}(\sigma^n) d\tau \right] \\ &= T_{i\ell}^n(ch_n) + \sum_{\mu=1}^{n-1} h_\mu^{\alpha_i} \sum_{j=0}^{s-1} J_j^i \left(\frac{t_{n-1} + ch_n - t_{\mu-1}}{h_\mu} \right) \gamma_{ij}(\sigma^\mu) + h_n^{\alpha_i} \sum_{j=0}^{s-1} I_j^{\alpha_i} P_j^i(c) \gamma_{ij}(\sigma^n) \\ &\equiv \phi_i^n(ch_n) + h_n^{\alpha_i} \sum_{j=0}^{s-1} I_j^{\alpha_i} P_j^i(c) \gamma_{ij}(\sigma^n), \quad c \in [0, 1], \quad i = 1, \dots, \nu, \end{aligned} \quad (14)$$

having set, for $x \geq 1$,

$$J_j^i(x) := \frac{1}{\Gamma(\alpha_i)} \int_0^1 (x - \tau)^{\alpha_i-1} P_j^i(\tau) d\tau, \quad j = 0, \dots, s-1, \quad i = 1, \dots, \nu, \quad (15)$$

and the *memory* term

$$\phi_i^n(ch_n) := T_{i\ell}^n(ch_n) + \sum_{\mu=1}^{n-1} h_\mu^{\alpha_i} \sum_{j=0}^{s-1} J_j^i \left(\frac{t_{n-1} + ch_n - t_{\mu-1}}{h_\mu} \right) \gamma_{ij}(\sigma^\mu), \quad c \in [0, 1], \quad i = 1, \dots, \nu. \quad (16)$$

Remark 1 For the efficient numerical evaluation of the integrals $I^{\alpha_i} P_j^i(c)$ in (7), and $J_j^i(x)$ in (15), we refer to [9, Section 3.2].

It must be emphasized that, since the memory term only depends on the past integration steps, according to (13)–(16) the discrete problem at step n consists in finding the $s\nu$ Fourier coefficients:

$$\gamma_{ij}(\sigma^n) = \int_0^1 \omega_i(c) P_j^i(c) f_i(\sigma^n(ch_n)) dc, \quad j = 0, \dots, s-1, \quad i = 1, \dots, \nu. \quad (17)$$

In more details, by setting hereafter $I_r \in \mathbb{R}^{r \times r}$ the identity matrix,

$$\mathbf{1}_r = (1, \dots, 1)^\top \in \mathbb{R}^r, \quad \boldsymbol{\alpha} = (\alpha_1, \dots, \alpha_\nu)^\top \in \mathbb{R}^\nu,$$

introducing the vectors and functions, with \otimes denoting the Kronecker product,

$$\begin{aligned} \gamma_i(\sigma^n) &= \begin{pmatrix} \gamma_{i0}(\sigma^n) \\ \vdots \\ \gamma_{i,s-1}(\sigma^n) \end{pmatrix} \in \mathbb{R}^{sm_i}, \quad i = 1, \dots, \nu, \\ \gamma(\sigma^n) &= \begin{pmatrix} \gamma_1(\sigma^n) \\ \vdots \\ \gamma_\nu(\sigma^n) \end{pmatrix} \in \mathbb{R}^{sm}, \\ P^i(c) &= \begin{pmatrix} P_0^i(c) & & \\ & \ddots & \\ & & P_{s-1}^i(c) \end{pmatrix} \otimes I_{m_i} \in \mathbb{R}^{sm_i \times sm_i}, \quad i = 1, \dots, \nu, \\ P(c) &= \begin{pmatrix} P^1(c) & & \\ & \ddots & \\ & & P^\nu(c) \end{pmatrix} \in \mathbb{R}^{sm \times sm}, \\ I^{\alpha_i} P^i(c) &= (I^{\alpha_i} P_0^i(c), \dots, I^{\alpha_i} P_{s-1}^i(c)) \otimes I_{m_i} \in \mathbb{R}^{m_i \times sm_i}, \quad i = 1, \dots, \nu, \end{aligned} \quad (18)$$

and

$$\begin{aligned}
h_n^\alpha &= \begin{pmatrix} h_n^{\alpha_1} I_{m_1} & & \\ & \ddots & \\ & & h_n^{\alpha_\nu} I_{m_\nu} \end{pmatrix} \in \mathbb{R}^{m \times m}, \\
I^\alpha P(c) &= \begin{pmatrix} I^{\alpha_1} P^1(c) & & \\ & \ddots & \\ & & I^{\alpha_\nu} P^\nu(c) \end{pmatrix} \in \mathbb{R}^{m \times sm}, \\
\phi^n(ch_n) &= \begin{pmatrix} \phi_1^n(ch_n) \\ \vdots \\ \phi_\nu^n(ch_n) \end{pmatrix} \in \mathbb{R}^m,
\end{aligned} \tag{19}$$

and taking into account that

$$\sigma^n(ch_n) = \phi^n(ch_n) + h_n^\alpha I^\alpha P(c) \gamma(\sigma^n), \tag{20}$$

one has that (17) can be rewritten as:

$$\begin{aligned}
\gamma_{ij}(\sigma^n) &= \int_0^1 \omega_i(c) P_j^i(c) f_i(\phi^n(ch_n) + h_n^\alpha I^\alpha P(c) \gamma(\sigma^n)) dc, \\
j &= 0, \dots, s-1, \quad i = 1, \dots, \nu.
\end{aligned} \tag{21}$$

This problem, in turn, can be cast in vector form as

$$\gamma(\sigma^n) = \int_0^1 \boldsymbol{\omega}(c) P(c) \mathbf{f}(\phi^n(ch_n) + h_n^\alpha I^\alpha P(c) \gamma(\sigma^n)) dc, \tag{22}$$

having set

$$\begin{aligned}
\mathbf{f}(\sigma) &= \begin{pmatrix} f_1(\sigma) \\ \vdots \\ f_\nu(\sigma) \end{pmatrix} \otimes \mathbf{1}_s \in \mathbb{R}^{sm}, \\
\boldsymbol{\omega}(c) &= \begin{pmatrix} \omega_1(c) I_{m_1} & & \\ & \ddots & \\ & & \omega_\nu(c) I_{m_\nu} \end{pmatrix} \otimes I_s \in \mathbb{R}^{sm \times sm}.
\end{aligned} \tag{23}$$

However, in order to derive a practical numerical method, the $s\nu$ Fourier coefficients (21) (i.e., (22)) need to be approximated by suitable quadrature rules. In the case where in (1) $\nu = 1$, this can be efficiently done by using a Gauss-Jacobi quadrature, defined at the zeros of the corresponding k th Jacobi polynomial: this results into a FHBVM(k, s) method. In the following sections, we study the extension to the case $\nu > 1$.

3 Extending FHBVMs to the multi-order case

The straightforward extension of FHBVMs to cope with problem (1), consists in discretizing the integrals involved in the Fourier coefficients (21) at the n th integration step, by means of a corresponding Gauss-Jacobi quadrature. In more details, for a suitable $k \geq s$, one approximates (21) with the order $2k$ interpolatory quadrature rule defined at the zeros c_ρ^i , $\rho = 1, \dots, k$, of $P_k^i(c)$, with corresponding weights $\{b_\rho^i\}$:

$$\gamma_{ij}(\sigma^n) \approx \gamma_{ij}^n = \sum_{\rho=1}^k b_\rho^i P_j^i(c_\rho^i) f_i(\phi^n(c_\rho^i h_n) + h_n^\alpha I^\alpha P(c_\rho^i) \gamma^n),$$

$$j = 0, \dots, s-1, \quad i = 1, \dots, \nu, \quad (24)$$

having set (compare with (18))

$$\gamma^n = \begin{pmatrix} \gamma_1^n \\ \vdots \\ \gamma_\nu^n \end{pmatrix}, \quad \gamma_i^n = \begin{pmatrix} \gamma_{i0}^n \\ \vdots \\ \gamma_{i,s-1}^n \end{pmatrix}, \quad i = 1, \dots, \nu. \quad (25)$$

This results into a FHBVM(k, s) method [8], having order at least s . In particular, the choice $k = s$, provides a collocation method. Moreover, a spectrally accurate solution can be achieved, by choosing $s \gg 1$, in view of (10). This is exactly the strategy used in the two Matlab[®] codes `fhbvm` and `fhbvm2`, implementing a FHBVM(20,22) and a FHBVM(22,22) method, respectively, designed for the case $\nu = 1$. In the case $\nu > 1$, however, one needs to evaluate the memory term, $\phi^n(ch_n)$, at the $k\nu$ abscissae

$$c_\rho^i, \quad \rho = 1, \dots, k, \quad i = 1, \dots, \nu. \quad (26)$$

This is a quite expensive part of the computational cost since, as it can be guessed from (16), all the information *ab initio* has to be computed for each abscissa in (26). Consequently, having ν different sets of abscissae is not a welcome news.

A different approach consists in looking for a set of suitable abscissae, c_1, \dots, c_k , such that the interpolatory quadrature rules defined over them are exact for polynomials of degree $2s-1$ (as it happens for the Gauss-Jacobi quadratures with $k = s$), for all the given weighting functions appearing in (21). I.e.,²

$$\forall g \in \Pi_{2s-1} : \int_0^1 \omega_i(c) g(c) dc = \sum_{\rho=1}^k b_\rho^i g(c_\rho), \quad i = 1, \dots, \nu, \quad (27)$$

where, for the sake of brevity, we continue denoting by $\{b_\rho^i\}$ the weights of the new quadratures. This is equivalent to find a family of polynomials $\{\pi_k\}$, such that, for a suitable $q \in \mathbb{N}$,

$$\pi_k(c_\rho) = 0, \quad \rho = 1, \dots, k, \quad \int_0^1 \omega_i(c) \pi_k(c) c^j dc = 0, \quad j = 0, \dots, q-1, \quad i = 1, \dots, \nu. \quad (28)$$

This is a particular instance of a family of so-called *multiple orthogonal polynomials (MOPs)* [54, 19], which we shall briefly sketch in the next section. In particular, in the case of multiple Jacobi weights, as in our case, such abscissae are known as *Jacobi-Piñeiro abscissae* [34].

²Hereafter, Π_m will denote the vector space of polynomials of degree at most m .

We observe that, in case (27)–(28) hold true, then we can compute³

$$\begin{aligned} \gamma_{ij}(\sigma^n) &\approx \gamma_{ij}^n = \sum_{\rho=1}^k b_\rho^i P_j^i(c_\rho) f_i(\phi^n(c_\rho h_n) + h_n^\alpha I^\alpha P(c_\rho) \gamma^n), \\ j &= 0, \dots, s-1, \quad i = 1, \dots, \nu, \end{aligned} \quad (29)$$

in place of (24). In such a way, we need to compute the memory term $\phi^n(ch_n)$ only at *one set* of k abscissae, instead of ν sets.

Remark 2 We observe that, when using (29) in place of (24), also the polynomials $P_j^i(c)$, and the corresponding integrals $I^{\alpha_i} P_j^i(c)$, $j = 0, \dots, s-1$, $i = 1, \dots, \nu$, are evaluated at *only one set* of abscissae, c_1, \dots, c_k . Conversely, in the case of (24), they need to be evaluated at ν different sets of abscissae, and this impacts unfavorably also in the implementation of the nonlinear iteration, as we shall sketch later in Section 5.

4 Multiple Orthogonal Polynomials (MOPs)

To begin with, the aim is that of computing a set of abscissae c_1, \dots, c_k , satisfying (28), for a suitable k to be determined. To this end, the following result holds true.

Theorem 1 Assume (28) holds true. Then the interpolatory quadratures with weights

$$b_\rho^i = \int_0^1 \omega_i(c) L_{\rho k}(c) dc, \quad L_{\rho k}(c) = \prod_{\iota \neq \rho} \frac{c - c_\iota}{c_\rho - c_\iota}, \quad \rho = 1, \dots, k, \quad i = 1, \dots, \nu,$$

satisfy

$$\int_0^1 \omega_i(c) g(c) dc = \sum_{\rho=1}^k b_\rho^i g(c_\rho), \quad i = 1, \dots, \nu, \quad \forall g \in \Pi_{k+q-1}.$$

Proof See [6, Theorem 1]. \square

Consequently, in order for this approach to reduce to the standard one [8, 11], when $\nu = 1$, hereafter we require:

$$k = \nu q, \quad k + q - 1 \geq 2s - 1, \quad (30)$$

so that all the quadratures (c_ρ, b_ρ^i) , $i = 1, \dots, \nu$, have at least order $2s$. Therefore, the following result is proved.

Corollary 1 The conditions (30) are satisfied, provided that⁴

$$q = \left\lceil \frac{2s}{\nu + 1} \right\rceil \quad \Rightarrow \quad k = \nu \left\lceil \frac{2s}{\nu + 1} \right\rceil. \quad (31)$$

Table 1 shows the values of k for $s = 22$, which is the value considered in the code `fhbvm2` [11].

³Of course, the weights $\{b_\rho^i\}$ are not the same as those in (24) but, instead, are those in (27).

⁴Hereafter, $\lceil \cdot \rceil$ and $\lfloor \cdot \rfloor$ will denote the ceiling and floor functions, respectively.

Table 1: Values of k according to (31) for increasing values of ν , for $s = 22$.

ν	1	2	3	4	5
k	22	30	33	36	40

Consequently, the problem is that of finding the zeros of the polynomial $\pi_k(c)$ in (28). A straightforward approach, to determine such a polynomial, consists in expressing it w.r.t. the power basis,

$$\pi_k(c) = \sum_{\iota=0}^k a_\iota c^{k-\iota}, \quad a_0 = 1,$$

and impose the k orthogonality conditions (28) (with $k = \nu q$, according to (30)). These orthogonality conditions, by setting hereafter

$$(f(c), g(c))_i = \int_0^1 \omega_i(c) f(c) g(c) dc, \quad i = 1, \dots, \nu, \quad (32)$$

read

$$\begin{pmatrix} (c^0, c^0)_1 & \dots & (c^0, c^{k-1})_1 \\ \vdots & & \vdots \\ (c^{q-1}, c^0)_1 & \dots & (c^{q-1}, c^{k-1})_1 \\ \vdots & & \vdots \\ (c^0, c^0)_\nu & \dots & (c^0, c^{k-1})_\nu \\ \vdots & & \vdots \\ (c^{q-1}, c^0)_\nu & \dots & (c^{q-1}, c^{k-1})_\nu \end{pmatrix} \begin{pmatrix} a_k \\ \vdots \\ a_1 \end{pmatrix} = - \begin{pmatrix} (c^0, c^k)_1 \\ \vdots \\ (c^{q-1}, c^k)_1 \\ \vdots \\ (c^0, c^k)_\nu \\ \vdots \\ (c^{q-1}, c^k)_\nu \end{pmatrix}.$$

Nevertheless, such linear system of k equations has the pitfall of having a badly conditioned coefficient matrix and is, therefore, not practically useful to recover $\pi_k(c)$. A different approach consists in deriving this polynomial as the k th one in the sequence $\{\pi_j\}_{j \geq 0}$ of monic polynomials satisfying the recurrence [42]⁵

$$\pi_j(c) = c\pi_{j-1}(c) - \sum_{i=\max(1, j-\nu)}^j a_{ji} \pi_{i-1}(c), \quad j = 1, 2, \dots, k, \quad \pi_0(c) \equiv 1. \quad (33)$$

This can be cast in vector form as

$$H_k \begin{pmatrix} \pi_0(c) \\ \pi_1(c) \\ \vdots \\ \vdots \\ \pi_{k-1}(c) \end{pmatrix} = c \begin{pmatrix} \pi_0(c) \\ \pi_1(c) \\ \vdots \\ \vdots \\ \pi_{k-1}(c) \end{pmatrix} - \begin{pmatrix} 0 \\ \vdots \\ \vdots \\ 0 \\ \pi_k(c) \end{pmatrix}, \quad (34)$$

⁵The notation has been slightly modified, w.r.t. [42], in order to have a more “familiar” enumeration of the entries of matrix H_k in (35).

with $H_k \in \mathbb{R}^{k \times k}$ a lower Hessenberg matrix,

$$H_k = \begin{pmatrix} a_{11} & 1 & & & \\ \vdots & \ddots & \ddots & & \\ a_{\nu+1,1} & \cdots & a_{\nu+1,\nu+1} & 1 & \\ & \ddots & & \ddots & \ddots \\ & & a_{k-1,k-1-\nu} & \cdots & a_{k-1,k-1} & 1 \\ & & & a_{k,k-\nu} & \cdots & a_{kk} \end{pmatrix}. \quad (35)$$

From (34) one deduces that $\pi_k(c_\rho) = 0$, $\rho = 1, \dots, k$, iff $c_\rho \in \sigma(H_k)$, with (right) eigenvectors respectively given by:

$$\begin{pmatrix} \pi_0(c_\rho) \\ \vdots \\ \pi_{k-1}(c_\rho) \end{pmatrix}, \quad \rho = 1, \dots, k. \quad (36)$$

The coefficients $\{a_{ji}\}$, in turn, if $j \in \{1, \dots, k\}$ is such that

$$j = r\nu + \mu, \quad \text{with} \quad \mu \in \{0, \dots, \nu - 1\}, \quad (37)$$

are computed by imposing that, by using the notation (32),⁶

$$\begin{aligned} (\pi_j(c), c^\rho)_i &= 0, & \rho = 0, \dots, r, & & i = 1, \dots, \mu, \\ (\pi_j(c), c^\rho)_i &= 0, & \rho = 0, \dots, r-1, & & i = \mu+1, \dots, \nu, \end{aligned}$$

which is clearly equivalent to require:

$$\begin{aligned} (\pi_j(c), \pi_\rho(c))_i &= 0, & \rho = 0, \dots, r, & & i = 1, \dots, \mu, \\ (\pi_j(c), \pi_\rho(c))_i &= 0, & \rho = 0, \dots, r-1, & & i = \mu+1, \dots, \nu. \end{aligned} \quad (38)$$

By setting, with reference to (37),

$$\xi(j) = \begin{cases} \mu, & \text{if } \mu > 0, \\ \nu, & \text{if } \mu = 0, \end{cases} \quad (39)$$

this results into [42]:

$$\begin{aligned} a_{ji} &= \frac{\left(c\pi_{j-1}(c) - \sum_{\ell=\max(1,j-\nu)}^{i-1} a_{j\ell} \pi_{\ell-1}(c), \pi_{\lfloor \frac{i-1}{\nu} \rfloor}(c) \right)_{\xi(i)}}{\left(\pi_{i-1}(c), \pi_{\lfloor \frac{i-1}{\nu} \rfloor}(c) \right)_{\xi(i)}}, \\ i &= \max(1, j-\nu), \dots, j, \quad j = 1, \dots, k. \end{aligned} \quad (40)$$

In fact, the following result holds true.

⁶Of course, when $r-1 < 0$, it is meant that the corresponding orthogonality condition is void.

Theorem 2 *By considering $k = q\nu$, according to (30), the family of polynomials $\{\pi_1, \dots, \pi_k\}$, defined by (33)–(37) and (39)–(40), satisfies the orthogonality conditions (38) (see (32)).*

Proof Following an induction argument on the index j varying on ν consecutive values, for $j = 1$, one has

$$\pi_1(c) = c - a_{11}, \quad a_{11} = \frac{(c, 1)_1}{(1, 1)_1},$$

so that (38) holds true with $r = 0$ and $\mu = 1$. A straightforward induction argument, shows that for $j = 2, \dots, \nu$, from (33) one obtains:

$$(\pi_j(c), \pi_0(c))_i = 0 \quad \Rightarrow \quad a_{ji} = \frac{\left(c\pi_{j-1}(c) - \sum_{\iota=1}^{i-1} a_{j\iota}\pi_{\iota-1}(c), \pi_0(c)\right)_i}{(\pi_{i-1}(c), \pi_0(c))_i}, \quad i = 1, \dots, j,$$

which matches (40), as required. Next, let us suppose (38) holds true up to $j = r\nu$, $r \geq 1$, and prove for

$$j = r\nu + \mu, \quad \mu = 1, \dots, \nu. \quad (41)$$

Let us start with $\mu = 1$. Clearly,

$$j = r\nu + 1 \quad \Rightarrow \quad \xi(i) = 1, \dots, \nu, 1, \quad \text{as} \quad i = j - \nu, \dots, j - 1, j. \quad (42)$$

Moreover, we know that (see (33))

$$i - 1 \in \{j - \nu - 1, \dots, j - 1\} = \{(r - 1)\nu, \dots, r\nu\},$$

so that, by induction hypothesis, if $i - 1 = (r - 1)\nu + \eta$, $\eta = 0, \dots, \nu$, then the following orthogonality conditions hold true:⁷

$$\begin{aligned} (\pi_{j-\nu}(c), \pi_\rho(c))_\iota &= 0, & \rho = 0, \dots, r - 2, & \quad \iota = 1, \dots, \nu, & \quad (\text{i.e., } \eta = 0), \\ (\pi_{i-1}(c), \pi_\rho(c))_\iota &= 0, & \rho = 0, \dots, r - 1, & \quad \iota = 1, \dots, \eta, & \quad (43) \\ (\pi_{i-1}(c), \pi_\rho(c))_\iota &= 0, & \rho = 0, \dots, r - 2, & \quad \iota = \eta + 1, \dots, \nu, & \quad \eta = 1, \dots, \nu - 1, \\ (\pi_{j-1}(c), \pi_\rho(c))_\iota &= 0, & \rho = 0, \dots, r - 1, & \quad \iota = 1, \dots, \nu, & \quad (\text{i.e., } \eta = \nu). \end{aligned}$$

Next, according to (38), let us impose that π_j satisfies the following orthogonality conditions,

$$\begin{aligned} (\pi_j(c), \pi_\rho(c))_i &= 0, & \rho = 0, \dots, r - 1, & \quad i = 1, \dots, \nu, \\ (\pi_j(c), \pi_r(c))_1 &= 0, \end{aligned}$$

which, by virtue of (43), reduce to

$$\begin{aligned} (\pi_j(c), \pi_{r-1}(c))_i &= 0, & i = 1, \dots, \nu, \\ (\pi_j(c), \pi_r(c))_1 &= 0. \end{aligned} \quad (44)$$

⁷Clearly, if $r - 2 < 0$, the corresponding orthogonality condition is void.

Imposing such conditions in the given order, then gives, according to (42),

$$a_{j,j-\nu+\eta} = \frac{\left(c\pi_{j-1}(c) - \sum_{\iota=j-\nu}^{j-\nu+\eta-1} a_{j\iota}\pi_{\iota-1}(c), \pi_{r-1}(c)\right)_{\eta+1}}{(\pi_{j-\nu+\eta-1}(c), \pi_{r-1}(c))_{\eta+1}}, \quad \eta = 0, \dots, \nu-1,$$

and

$$a_{jj} = \frac{\left(c\pi_{j-1}(c) - \sum_{\iota=j-\nu}^{j-1} a_{j\iota}\pi_{\iota-1}(c), \pi_r(c)\right)_1}{(\pi_{j-1}(c), \pi_r(c))_1},$$

respectively, which match (40) when $j = r\nu + 1$. The subsequent values of μ in (41) can be handled by means of similar arguments. In fact, for $\mu = 2, \dots, \nu$, one needs to impose (compare with (44)):

$$\begin{aligned} (\pi_j(c), \pi_{r-1}(c))_i &= 0, & i = \mu, \dots, \nu, \\ (\pi_j(c), \pi_r(c))_i &= 0, & i = 1, \dots, \mu. \end{aligned}$$

From these orthogonality conditions, by considering that, for $i = j-\nu, \dots, j$, $\xi(i) = \mu, \dots, \nu, 1, \dots, \mu$, one eventually obtains:

$$a_{j,j-\nu+\eta} = \frac{\left(c\pi_{j-1}(c) - \sum_{\iota=j-\nu}^{j-\nu+\eta-1} a_{j\iota}\pi_{\iota-1}(c), \pi_{r-1}(c)\right)_{\eta+\mu}}{(\pi_{j-\nu+\eta-1}(c), \pi_{r-1}(c))_{\eta+\mu}}, \quad \eta = 0, \dots, \nu-\mu,$$

and

$$a_{j,j-\nu+\eta} = \frac{\left(c\pi_{j-1}(c) - \sum_{\iota=j-\nu}^{j-\nu+\eta-1} a_{j\iota}\pi_{\iota-1}(c), \pi_r(c)\right)_{\eta-\nu+\mu}}{(\pi_{j-\nu+\eta-1}(c), \pi_r(c))_{\eta-\nu+\mu}}, \quad \eta = \nu - \mu + 1, \dots, \nu,$$

which, again, are consistent with (40). Consequently, the statement follows. \square

Remark 3 *The proof of Theorem 2 has been reported for a twofold reason:*

1. *a formal proof, in the general case, was still lacking in the literature (usually, only the case $\nu = 2$ is worked out);*
2. *the proof itself provides operative guidelines for efficiently deriving the entries of matrix H_k in (35).*

4.1 Some computational remarks

In order to derive a practical numerical method, one needs:

1. at first, compute the integrands involved in (40) (see (32)). By taking into account (30)–(31), one has that the integrands are polynomials of degree at most

$$k-1 + \left\lfloor \frac{k-1}{\nu} \right\rfloor = \nu q - 1 + \left\lfloor \frac{\nu q - 1}{\nu} \right\rfloor = \nu q + q - 2 = (\nu + 1)q - 2 = (\nu + 1) \left\lceil \frac{2s}{\nu + 1} \right\rceil - 2.$$

Table 2: Values of φ in (45) for increasing values of ν , for $s = 22$.

ν	1	2	3	4	5
φ	22	22	22	22	24

Consequently, they can be computed exactly (up to round-off errors) by using a corresponding Gauss-Jacobi quadrature over

$$\varphi = \left\lceil \frac{\nu+1}{2} \left\lceil \frac{2s}{\nu+1} \right\rceil - \frac{1}{2} \right\rceil \quad (45)$$

abscissae. For sake of completeness, in Table 2 we list a few values of φ , for the case $s = 22$ considered in the code `fhbvm2`, for increasing values of ν ;

- secondly, matrix H_k in (34)–(35) must be balanced, in order to improve accuracy in numerically finding its eigenvalues. For this purpose, a recent strategy, proposed in [34], consists in a diagonal scaling that symmetrizes the tridiagonal part of H_k . Additional computational aspects have been also considered in [35, 53].

5 Solving the discrete problems

As sketched above (see (29)), the discrete problem to be solved at the n th integration step consists in:

$$\gamma_{ij}^n = \sum_{\rho=1}^k b_{\rho}^i P_j^i(c_{\rho}) f_i(\phi^n(c_{\rho} h_n) + h_n^{\alpha} I^{\alpha} P(c_{\rho}) \gamma^n), \quad j = 0, \dots, s-1, \quad i = 1, \dots, \nu, \quad (46)$$

where the notations (18)–(19) and (25) have been used. By using notations (18)–(19) and (25) again, we can recast (46) as:

$$\gamma_i^n = (\mathcal{P}_s^i)^{\top} \Omega_i \cdot f_i(\phi^n(c h_n) + h_n^{\alpha} \mathcal{I}_s^{\alpha} \gamma^n), \quad i = 1, \dots, \nu, \quad (47)$$

where we have set

$$\begin{aligned} \mathbf{c} &= \begin{pmatrix} c_1 \\ \vdots \\ c_k \end{pmatrix} \in \mathbb{R}^k, \quad \phi^n(c h_n) = \begin{pmatrix} \phi^n(c_1 h_n) \\ \vdots \\ \phi^n(c_k h_n) \end{pmatrix} \in \mathbb{R}^{km}, \\ \mathbf{h}_n^{\alpha} &= I_k \otimes h_n^{\alpha} \in \mathbb{R}^{km \times km}, \end{aligned} \quad (48)$$

additionally,

$$\begin{aligned}
\Omega_i &= \begin{pmatrix} b_1^i & & \\ & \ddots & \\ & & b_k^i \end{pmatrix} \otimes I_{m_i} \in \mathbb{R}^{km_i \times km_i}, \\
\mathcal{P}_s^i &= \begin{pmatrix} P_0^i(c_1) & \dots & P_{s-1}^i(c_1) \\ \vdots & & \vdots \\ P_0^i(c_k) & \dots & P_{s-1}^i(c_k) \end{pmatrix} \otimes I_{m_i} \in \mathbb{R}^{km_i \times sm_i}, \\
\mathcal{I}_s^\alpha &= \begin{pmatrix} I^\alpha P(c_1) \\ \vdots \\ I^\alpha P(c_k) \end{pmatrix} \in \mathbb{R}^{km \times sm},
\end{aligned} \tag{49}$$

and

$$f_i(\phi^n(ch_n) + \mathbf{h}_n^\alpha \mathcal{I}_s^\alpha \gamma^n) = \begin{pmatrix} f_i(\phi^n(c_1 h_n) + h_n^\alpha I^\alpha P(c_1) \gamma^n) \\ \vdots \\ f_i(\phi^n(c_k h_n) + h_n^\alpha I^\alpha P(c_k) \gamma^n) \end{pmatrix}, \quad i = 1, \dots, \nu. \tag{50}$$

By further introducing the notation

$$\mathcal{P}_s = \begin{pmatrix} \mathcal{P}_s^1 & & \\ & \ddots & \\ & & \mathcal{P}_s^\nu \end{pmatrix} \in \mathbb{R}^{km \times sm}, \quad \Omega = \begin{pmatrix} \Omega_1 & & \\ & \ddots & \\ & & \Omega_\nu \end{pmatrix} \in \mathbb{R}^{km \times km}, \tag{51}$$

and

$$f(\phi^n(ch_n) + \mathbf{h}_n^\alpha \mathcal{I}_s^\alpha \gamma^n) = \begin{pmatrix} f_1(\phi^n(ch_n) + \mathbf{h}_n^\alpha \mathcal{I}_s^\alpha \gamma^n) \\ \vdots \\ f_\nu(\phi^n(ch_n) + \mathbf{h}_n^\alpha \mathcal{I}_s^\alpha \gamma^n) \end{pmatrix} \in \mathbb{R}^{km}, \tag{52}$$

one eventually obtains that (47) can be compactly written as:

$$\gamma^n = \mathcal{P}_s^\top \Omega \cdot f(\phi^n(ch_n) + \mathbf{h}_n^\alpha \mathcal{I}_s^\alpha \gamma^n). \tag{53}$$

From this formulation, the following result follows.

Theorem 3 *Assume f is Lipschitz continuous. Then, for all sufficiently small $h_n > 0$ problem (53) has a unique solution.*

Proof In fact, from (18)–(19) and (51), it follows that, provided that, for any suitable matrix norm,

$$h_n^{\min_i \alpha_i} L \|\mathcal{P}_s^\top \Omega\| \|\mathcal{I}_s^\alpha\| < 1, \tag{54}$$

with L the local Lipschitz constant, the iteration

$$\gamma^{n,r+1} = \mathcal{P}_s^\top \Omega \cdot f(\phi^n(ch_n) + \mathbf{h}_n^\alpha \mathcal{I}_s^\alpha \gamma^{n,r}), \quad r = 0, 1, \dots, \quad \gamma^{n,0} = \mathbf{0}, \tag{55}$$

is a contraction. \square

Remark 4 *Even though the fixed-point iteration (55) is straightforward and easy to implement, nevertheless, the condition (54) may be too restrictive, if $L \gg 1$: in such a case, a Newton-type iteration has to be used. This aspect will be studied in the next two subsections 5.1 and 5.2.*

5.1 The case $\nu = 1$

In the case $\nu = 1$, i.e., when only one fractional derivative occurs, a very efficient Newton-type iteration can be considered, i.e., the so-called *blended iteration*, at first derived in the ODE case [7, 16, 17, 15, 13], and then adapted for the FDE case [9]. We briefly sketch it, for sake of completeness. In such a case, from (18)–(19), (48)–(49), and (51), with $\nu = 1$, considering that $m_1 = m$, it follows that (53) becomes

$$\gamma_1^n = (\mathcal{P}_s^1)^\top \Omega_1 \cdot f_1(\phi^n(\mathbf{c}h_n) + h_n^{\alpha_1} \mathcal{I}_s^{\alpha_1} \gamma_1^n).$$

Consequently, we need to solve the problem

$$G(\gamma) := \gamma - (\mathcal{P}_s^1)^\top \Omega_1 \cdot f_1(\phi^n(\mathbf{c}h_n) + h_n^{\alpha_1} \mathcal{I}_s^{\alpha_1} \gamma) = 0.$$

Some algebra shows that the simplified Newton iteration, for its solution, reads:⁸

$$\begin{aligned} \text{solve: } [I_{sm} - h_n^{\alpha_1} X_{11} \otimes f_1'(\phi^n(0))] \delta^j &= -G(\gamma^j), \\ \text{update: } \gamma^{j+1} &= \gamma^j + \delta^j, \quad j = 0, 1, \dots, \end{aligned} \quad (56)$$

with

$$\begin{aligned} X_{11} &= \begin{pmatrix} P_0^1(c_1) & \dots & P_0^1(c_k) \\ \vdots & & \vdots \\ P_{s-1}^1(c_1) & \dots & P_{s-1}^1(c_k) \end{pmatrix} \begin{pmatrix} b_1^1 & & \\ & \ddots & \\ & & b_k^1 \end{pmatrix} \begin{pmatrix} I^{\alpha_1} P_0^1(c_1) & \dots & I^{\alpha_1} P_{s-1}^1(c_1) \\ \vdots & & \vdots \\ I^{\alpha_1} P_0^1(c_k) & \dots & I^{\alpha_1} P_{s-1}^1(c_k) \end{pmatrix} \\ &\in \mathbb{R}^{s \times s}, \end{aligned} \quad (57)$$

where the initial condition $\gamma^0 = 0$ can be conveniently used. The iteration (56)–(57), though straightforward, requires to factor the matrix

$$[I_{sm} - h_n^{\alpha_1} X_{11} \otimes f_1'(\phi^n(0))] \in \mathbb{R}^{sm \times sm}.$$

The associated *blended iteration*, formally obtained by combining (56) with the equivalent formulation

$$\rho_{11} [X_{11}^{-1} \otimes I_m - h_n^{\alpha_1} I_s \otimes f_1'(\phi^n(0))] \delta_j = -\rho_{11} (X_{11}^{-1} \otimes I_m) G(\gamma^j),$$

with weights θ^n and $I_{sm} - \theta^n$, respectively, where

$$\theta^n = I_s \otimes [I_m - \rho_{11} h_n^{\alpha_1} f_1'(\phi^n(0))]^{-1}$$

and $\rho_{11} > 0$ is a suitable parameter depending on the spectrum of matrix X_{11} [9], reads, as follows:

$$\begin{aligned} \text{set: } \eta_j &= -G(\gamma^j) \\ \hat{\eta}_j &= \rho_{11} (X_{11}^{-1} \otimes I_m) \eta_j \\ \gamma^{j+1} &= \gamma^j - \theta^n [\hat{\eta}_j + \theta^n (\eta_j - \hat{\eta}_j)], \quad j = 0, 1, \dots \end{aligned} \quad (58)$$

Also in this case, one conveniently starts at $\gamma^0 = 0$. Clearly, this iteration only requires to factor the matrix

$$I_m - \rho_{11} h_n^{\alpha_1} f_1'(\phi^n(0)) \in \mathbb{R}^{m \times m}.$$

Unfortunately, this very effective approach, implemented in the Matlab[©] codes `fhbvm` [9] and `fhbbm2` [11], does not extend to the case $\nu > 1$.

⁸As is usual, f_1' denotes the Jacobian matrix of f_1 .

5.2 The case $\nu > 1$

To cope with this case, we need to rely on the straight simplified Newton iteration for solving (53), i.e.,

$$G(\gamma) := \gamma - \mathcal{P}_s^\top \Omega \cdot f(\phi^n(ch_n) + \mathbf{h}_n^\alpha \mathcal{I}_s^\alpha \gamma) = \mathbf{0},$$

which now reads:

$$\text{solve: } [I_{sm} - \mathcal{P}_s^\top \Omega \cdot (I_k \otimes f'(\phi^n(0))) \cdot \mathbf{h}_n^\alpha \mathcal{I}_s] \delta^j = -G(\gamma^j), \quad (59)$$

$$\text{update: } \gamma^{j+1} = \gamma^j + \delta^j, \quad j = 0, 1, \dots,$$

where, again, $\gamma^0 = \mathbf{0}$ is conveniently used. For sake of clarity, let us explain in detail the (block) structure of the matrix

$$\mathcal{P}_s^\top \Omega \cdot (I_k \otimes f'(\phi^n(0))) \cdot \mathbf{h}_n^\alpha \mathcal{I}_s \equiv \begin{pmatrix} h_n^{\alpha_1} X_{11} \otimes f_{11}^n & \dots & h_n^{\alpha_\nu} X_{1\nu} \otimes f_{1\nu}^n \\ \vdots & & \vdots \\ h_n^{\alpha_1} X_{\nu 1} \otimes f_{\nu 1}^n & \dots & h_n^{\alpha_\nu} X_{\nu\nu} \otimes f_{\nu\nu}^n \end{pmatrix} \in \mathbb{R}^{sm \times sm},$$

where, with reference to (1) and (52), for all $i, j = 1, \dots, \nu$:

$$f_{ij}^n = \frac{\partial}{\partial y_j} f_i(\phi^n(0)) \in \mathbb{R}^{m_i \times m_j},$$

and, generalizing (57),

$$X_{ij} = \begin{pmatrix} P_0^i(c_1) & \dots & P_0^i(c_k) \\ \vdots & & \vdots \\ P_{s-1}^i(c_1) & \dots & P_{s-1}^i(c_k) \end{pmatrix} \begin{pmatrix} b_1^i & & \\ & \ddots & \\ & & b_k^i \end{pmatrix} \begin{pmatrix} I^{\alpha_j} P_0^j(c_1) & \dots & I^{\alpha_j} P_{s-1}^j(c_1) \\ \vdots & & \vdots \\ I^{\alpha_j} P_0^j(c_k) & \dots & I^{\alpha_j} P_{s-1}^j(c_k) \end{pmatrix} \in \mathbb{R}^{s \times s}.$$

Clearly, in this case the $sm \times sm$ coefficient matrix in (59), i.e.,

$$I_{sm} - \begin{pmatrix} h_n^{\alpha_1} X_{11} \otimes f_{11}^n & \dots & h_n^{\alpha_\nu} X_{1\nu} \otimes f_{1\nu}^n \\ \vdots & & \vdots \\ h_n^{\alpha_1} X_{\nu 1} \otimes f_{\nu 1}^n & \dots & h_n^{\alpha_\nu} X_{\nu\nu} \otimes f_{\nu\nu}^n \end{pmatrix} \in \mathbb{R}^{sm \times sm}, \quad (60)$$

needs to be factored and, therefore, the computational cost is higher than in the case $\nu = 1$, where the more efficient *blended iteration* (58) can be used.

Remark 5 In case one uses the approach (24), instead of (29), for approximating the Fourier coefficients, the simplified Newton iteration would require to factor the matrix

$$I_{sm} - \begin{pmatrix} h_n^{\alpha_1} X_{11}^1 \otimes f_{11}^n & \dots & h_n^{\alpha_\nu} X_{1\nu}^1 \otimes f_{1\nu}^n \\ \vdots & & \vdots \\ h_n^{\alpha_1} X_{\nu 1}^\nu \otimes f_{\nu 1}^n & \dots & h_n^{\alpha_\nu} X_{\nu\nu}^\nu \otimes f_{\nu\nu}^n \end{pmatrix} \in \mathbb{R}^{sm \times sm},$$

in place of (60), with

$$X_{ij}^i = \begin{pmatrix} P_0^i(c_1^i) & \dots & P_0^i(c_k^i) \\ \vdots & & \vdots \\ P_{s-1}^i(c_1^i) & \dots & P_{s-1}^i(c_k^i) \end{pmatrix} \begin{pmatrix} b_1^i & & \\ & \ddots & \\ & & b_k^i \end{pmatrix} \begin{pmatrix} I^{\alpha_j} P_0^j(c_1^i) & \dots & I^{\alpha_j} P_{s-1}^j(c_1^i) \\ \vdots & & \vdots \\ I^{\alpha_j} P_0^j(c_k^i) & \dots & I^{\alpha_j} P_{s-1}^j(c_k^i) \end{pmatrix} \in \mathbb{R}^{s \times s}.$$

Consequently, for all $i = 1, \dots, \nu$, the i th block row depends on the corresponding set of Jacobi abscissae (i.e., the zeros of $P_k^i(c)$).

6 The code fhbvm2_2

The Matlab[®] code `fhbvm2_2` implements a FHBVM(22,22) method, using the approach described in the previous section, in the case $\nu \in \{1, 2\}$ in (1). The code may use a mixed-mesh (12), as described in [11], i.e.:

- either a *graded mesh*, where

$$h_n = h_1 r^{n-1}, \quad n = 1, \dots, N, \quad \text{with} \quad r > 1 \quad \text{s.t.} \quad h_1 \frac{r^N - 1}{r - 1} = T, \quad (61)$$

or

- a *uniform mesh*

$$h_n = h \equiv \frac{T}{N}, \quad n = 1, \dots, N, \quad (62)$$

or

- a *mixed-mesh* where, for a suitably chosen $\rho \in \mathbb{N}$, $\rho \geq 1$, and setting

$$r := \frac{\max\{2, \rho\}}{\max\{2, \rho\} - 1},$$

one has, for a suitable $\mu \in \mathbb{N}$, $\mu \geq 1$, and denoting $M := N - \mu + \rho$:

$$\begin{aligned} h_n &= h_1 r^{n-1}, & n = 1, \dots, \mu, & \quad \text{with} \quad h_1 \frac{r^\mu - 1}{r - 1} = \rho h, \\ h_n &= h \equiv \frac{T}{M}, & n = \mu + 1, \dots, N. & \end{aligned} \quad (63)$$

Of course, (63) reduces to either (62), when $\mu = \rho = 1$, or to (61), when $\mu = N > 1$. Moreover, as is clear [11]:

- (61) is appropriate when the vector field is nonsmooth at $t = 0$;
- (62) is appropriate when the vector field is smooth everywhere;
- (63) is appropriate when the vector field is nonsmooth at $t = 0$, but the solution becomes eventually periodic.

Concerning the evaluation of the abscissae and the weights for the quadrature(s):

- when $\nu = 1$, the Jacobi abscissae and weights are computed by adapting the companion Matlab[®] code of [29];
- when $\nu = 2$, the Jacobi-Piñero abscissae and weights are computed by adapting the companion Matlab[®] code of [34].

Concerning the nonlinear iteration:

- when $\nu = 1$, the more efficient *blended iteration* (58) is used (as an alternative to the fixed-point iteration (55), used whenever possible);
- when $\nu = 2$, the straight simplified-Newton iteration (59) is used (as an alternative to the fixed-point iteration (55), used whenever possible).

All the remaining implementation details are similar to those of the codes `fhbvm` and `fhbvm2`, as explained in [9] and [11], respectively. The new code `fhbvm2_2` can be downloaded at the same URL [56], where the previous codes are available as well.

The calling sequence of the code is

$$[\mathbf{t}, \mathbf{y}, \mathbf{etim}] = \text{fhbvm2_2}(\text{fun}, \mathbf{y0}, \mathbf{T}, \mathbf{M}, \mu, \mathbf{rho}) \quad (64)$$

In input, with reference to (1) and (63):⁹

- \mathbf{T} is the final time T ;
- \mathbf{M} contains the value M in (63) (this parameter is named \mathbf{N} , in the actual interface of the code);
- μ contains μ (this parameter is named \mathbf{nu} in the actual interface of the code);
- \mathbf{rho} contains ρ (this parameter is named \mathbf{n} in the actual interface of the code);
- $\mathbf{y0}$ is a $\ell \times m$ matrix with the initial conditions (row vectors);
- fun is the identifier of a function implementing the problem (1). In more detail:
 - `[alpha,m1] = fun()` returns α_1 , α_2 and m_1 . In case $\alpha_1 = \alpha_2$ or $\alpha_2 = 0$, m_1 is not used;
 - `fun(t,y)` returns the vector field (also in vector mode);
 - `fun(t,y,1)` returns the Jacobian matrix of f .

In output:

- \mathbf{t} is the used mesh (12);
- \mathbf{y} contains the computed approximations (row-wise);
- \mathbf{etim} is the elapsed time (in sec).

⁹Hereafter, in order to have the same calling sequence for both `fhbvm2` and `fhbvm2_2`, for this latter code, with reference to (64): \mathbf{M} is renamed \mathbf{N} , \mathbf{rho} is renamed \mathbf{n} , and μ is renamed \mathbf{nu} . As matter of fact, when possible, the two codes will be used with the same input arguments. See [12] for more details.

7 Numerical tests

Here, we report some comparisons among the following Matlab[©] codes, publicly available on the internet:

- **fde12** [27], implementing a second-order predictor-corrector method, based on fractional versions of the Adams methods, which can handle only the case $\nu = 1$ in (1). We shall consider the PECE implementation of the methods (**fde12**) and the one with 10 corrector iterations (**fde12-10**);
- **flmm2** [27], implementing fractional versions of the trapezoidal rule (**flmm2-1**), of the Newton-Gregory formula (**flmm2-2**), and of the BFD2 method (**flmm2-3**). This code can handle only the case $\nu = 1$ in (1), and will be used with the following parameters:
 - tolerance for the nonlinear iteration: **tol=1e-15**,
 - maximum number of nonlinear iterations per step: **maxit=1000**;
- **fde_pi12_pc** [27], implementing a second-order product-integration with predictor-corrector, which can handle multi-order FDEs. As with **fde12**, we shall consider the PECE implementation, and that with 10 iterations of the corrector (**fde_pi12_pc-10**);
- **fde_pi2_im** [27], implementing a second-order implicit product-integration of trapezoidal type, which can handle multi-order FDEs. It is used with the same parameters **tol** and **itmax** considered for **flmm2**;
- **fhbvm** [9], based on a FHBVM(22,20) method, which can handle only the case $\nu = 1$ in (1);
- **fhbvm2** [11], based on a FHBVM(22,22) method, which can handle only the case $\nu = 1$ in (1);
- the code **fhbvm2_2** here described, based on a FHBVM(22,22) method, which can handle the cases $\nu = 1$ and $\nu = 2$ in (1). In the case $\nu = 1$, it will be used with the same parameters used for **fhbvm2**.

We refer to [12] for a quick introduction to the codes **fde12**, **flmm2**, **fhbvm**, and **fhbvm2**. Moreover, the code **fde_pi12_pc** is a kind of multi-order extension of **fde12**, and **fde_pi2_im** is a kind of multi-order extension of **flmm2**, both couples of codes having a similar interface.¹⁰

All numerical tests have been done on a 12-core M4-pro Silicon based computer with 64GB of memory, using Matlab[©] Rel. 2025a.

When necessary, comparisons among the codes, on a given test problem, will be done by using a corresponding *work-precision diagram (WPD)*, where the execution time (measured in sec) is plotted against accuracy, measured in terms of *mixed-error significant computed digits (mescd)*, defined as follows:

$$\text{mescd} = \max \left\{ 0, -\log_{10} \max_n \|(y(t_n) - y_n) ./ (1 + |y(t_n)|)\|_{\infty} \right\},$$

with $y_n \approx y(t_n)$, this latter the reference solution, $|\cdot|$ the vector of the absolute values, and $./$ the component-wise division. As is clear, higher and higher accuracies are obtained by suitably tuning the parameters of the various codes.

The problems with $\nu = 1$ are taken from the FDE-Testset [12]: in particular, at the URL [57] Matlab[©] codes implementing them, and providing reference solutions, are available.

¹⁰These codes are available at the URL [58].

Problem 1

This is a *stiff* linear problem with only one fractional derivative. It is taken from [12, Problem 3], and at the URL [57] a corresponding Matlab[®] code, implementing the problem and providing the reference solution, is available:

$$y^{(0.5)} = \frac{1}{5} \begin{pmatrix} -92 & -87 \\ -58 & -63 \end{pmatrix} y - \frac{1}{10} \begin{pmatrix} 67 \\ 83 \end{pmatrix}, \quad t \in [0, 100], \quad y(0) = \begin{pmatrix} 5 \\ 10 \end{pmatrix}. \quad (65)$$

Based on the choices in [12], the following parameters are used for the various codes, to construct the corresponding WPD:

- `fde12`, `fde12-10`, `fde_pi12_pc`, `fde_pi12_pc-10`: $h = 10^{-i}$, $i = 4, 5, 6$;
- `flmm2-1`, `flmm2-2`, `flmm2-3`, `fde_pi2_im`: $h = 10^{-i}$, $i = 2, 3, 4, 5$;
- `fhbvm`: $M = 5, \dots, 10$;
- `fhbvm2`, `fhbvm2_2`: $nu = 50$, $n = 1$, $N = 10i$, $i = 5, \dots, 10$.

The corresponding WPD is reported in Figure 1, from which one may conclude that:

- `fde12` can reach an accuracy of less than 4 mescd in about 700 sec. `fde_pi12_pc` reaches a similar accuracy, but with a higher execution time (more than 1000 sec). For both codes, increasing the number of corrector iterations does not improve accuracy but only affects the execution time (in fact, more than 2000 sec are needed to achieve the same accuracy);
- `flmm2` can achieve about 5 mescd in about 1000 sec (the run with the fractional BDF2 is slightly less accurate), with a comparable execution time, whereas `fde_pi2_im` can reach less than 3 mescd;
- `fhbvm`, `fhbvm2`, and `fhbvm2_2` do have a comparable performance (13-14 mescd in about 0.1 sec). In particular, as is expected, `fhbvm2` and `fhbvm2_2` do have practically the same behavior.

Problem 2

This is a *stiffly oscillatory* linear problem with only one fractional derivative. It is taken from [12, Problem 4] and, at the URL [57], a corresponding Matlab[®] code, implementing the problem and providing the reference solution, is available:

$$y^{(0.5)} = \frac{1}{8} \begin{pmatrix} 41 & 41 & -38 & 40 & -2 \\ -79 & 81 & 2 & 0 & -2 \\ 20 & -60 & 20 & -20 & -8 \\ -22 & 58 & -24 & 20 & -4 \\ 1 & 1 & -2 & -4 & -2 \end{pmatrix} y, \quad t \in [0, 20], \quad y(0) = \begin{pmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{pmatrix}. \quad (66)$$

Based on [12], the following parameters are used for the various codes, to construct the corresponding WPD:

- `fde12`, `fde12-10`, `fde_pi12_pc`, `fde_pi12_pc-10`: $h = 10^{-i}$, $i = 5, 6$;

Figure 1: WPD for Problem (65).

Figure 2: WPD for Problem (66).

- **flmm2-1, flmm2-2, flmm2-3, fde_pi2_im**: $h = 10^{-i}$, $i = 4, 5$;
- **fhbvm**: $M = 100i$, $i = 3, 4, 5$;
- **fhbvm2, fhbvm2_2**: $nu = 50$, $n = 1$, $N = 100i$, $i = 3, 4, 5$.

The corresponding WPD is reported in Figure 2, from which one obtains that:

- **fde12** and **fde_pi12_pc** reach an accuracy of less than 2 mescd in more than 500 sec. Increasing the number of corrector iterations improves accuracy to about 3 mescd, but with a much higher execution time (about 2500 sec) for both codes;
- **flmm2** (all versions) and **fde_pi2_im** can achieve about 2 mescd in about 800 sec;
- **fhbvm** is the most accurate code, with about 11 mescd, with an execution time of about 60 sec;
- **fhbvm2** and **fhbvm2_2** do have a comparable performance (over 10 mescd in about 1 sec), as expected, due to the oscillatory nature of the solution [12].

Problem 3

The third problem is a multi-order variant of [12, Problem 7]:

$$\begin{aligned} y_1^{(\alpha_1)} &= s(t, \alpha_2, \beta)^2 - y_2^2 + g(t, \alpha_1, \beta), \\ y_2^{(\alpha_2)} &= -s(t, \alpha_1, \beta)^2 + y_1^2 + g(t, \alpha_2, \beta), \quad t \in [0, 2], \\ y_1(0) &= y_2(0) = 1, \end{aligned} \tag{67}$$

having solution $y_i(t) = s(t, \alpha_i, \beta)$, $i = 1, 2$, with

$$s(t, \alpha, \beta) = (1 - t^2)^2 + 4t^\alpha + (2 - 3t^{0.2})t^{\alpha+\beta},$$

and

$$g(t, \alpha, \beta) = \frac{24t^{4-\alpha}}{\Gamma(5-\alpha)} - \frac{4t^{2-\alpha}}{\Gamma(3-\alpha)} - 3t^{0.2+\beta} \frac{\Gamma(1.2+\alpha+\beta)}{\Gamma(1.2+\beta)} + 2t^\beta \frac{\Gamma(1+\alpha+\beta)}{\Gamma(1+\beta)} + 4\Gamma(1+\alpha).$$

We shall consider the values $\alpha_1 = 0.2$, $\alpha_2 = 0.4$, $\beta = 0.1$. The solution, and the corresponding vector field, are depicted in Figure 3.

The following parameters are used for the codes **fde12**, **flmm2**, and **fhbvm2_2**, which are the only ones that can be used, in this case:

- **fde_pi12_pc, fde_pi12_pc-10, fde_pi2_im**: $h = 10^{-i}$, $i = 5, 6, 7$;
- **fhbvm2_2**: $n = 2$, $nu = 100$, $N = 5i$, $i = 2, 3, 4, 5, 6$.

The obtained results are reported in the WPD in Figure 4, from which one may infer that:

- **fde_pi12_pc** and **fde_pi12_pc-10** can reach an accuracy of about 3 mescd in about 250 sec and 700 sec, respectively. Consequently, increasing the corrector iterations does not improve accuracy but only affects the execution time;
- **fde_pi2_im** reaches the same accuracy of about 3 mescd in about 10^4 sec;
- **fhbvm2_2** reaches full machine accuracy (more than 14 mescd) in about 0.3 sec.

Figure 3: Solution (upper-plot) and vector field (lower-plot) for Problem (67).

Figure 4: WPD for Problem (67).

Figure 5: WPD for Problem (68), $\alpha_1 = 0.7$, $\alpha_2 = 0.8$.

Problem 4

This problem is a multi-order fractional version of the Brusselator problem, adapted from [27, Problem (32)]:

$$\begin{aligned} y_1^{(\alpha_1)} &= A - (B + 1)y_1 + y_1^2 y_2, \\ y_2^{(\alpha_2)} &= B y_1 - y_1^2 y_2, \quad t \in [0, 100], \\ y_1(0) &= 1.2, \quad y_2(0) = 2.8, \end{aligned} \tag{68}$$

where we use the same parameters as in [27]: $A = 1$, $B = 3$, $\alpha_1 = 0.8$, and $\alpha_2 = 0.7$. The solution is depicted in Figure 6, both in the phase space and versus time, from which one infers that it approaches a limit cycle, thus becoming of periodic type: in the first plot, the circle denotes the initial point of the trajectory.

The following parameters are used for the codes `fde_pi12_pc`, `fde_pi12_im`, and `fhbvm2_2`, which are the only ones that can be used, in this case:

- `fde_pi12_pc`, `fde_pi12_pc-10`, `fde_pi12_im`: $h = 10^{-i}$, $i = 2, 3, 4, 5$;
- `fhbvm2_2`: $n = 1$, $nu = 50$, $N = 50i$, $i = 4, 5, 6$.

The obtained results are reported in Figure 5, where the accuracy w.r.t. a reference solution at the end point is reported. This latter has been evaluated numerically by using `fhbvm2_2` on 3 consecutive doubled meshes, resulting into:

$$y_1(100) \approx 1.706502172199, \quad y_2(100) \approx 1.940414058005.$$

From the obtained results, one concludes that:

- `fde_pi12_pc-10` reaches an accuracy of 7.5 mescd in about 25 sec, whereas `fde_pi12_pc` reaches about 7 mescd in 100 sec;
- `fde_pi12_im` reaches an accuracy of 7.5 sec in approximately 180 sec;
- `fhbvm2_2` reaches 13 mescd in less than 2 sec, independently of the stepsize used, as one expects from a spectrally accurate method.

Problem 5

As stressed in Section 5.1, the *blended iteration*, which can be used in the case $\nu = 1$ in (1), only requires to factor one matrix having the same size as that of the continuous problem. It has, therefore, a lower computational cost, w.r.t. the simplified Newton iteration, to be used in the case $\nu > 1$. The next example is aimed at assessing this fact. For this purpose, we shall use the code `fhbvm2_2` for solving problem (68) with the same parameters $A = 1$ and $B = 3$ used before, but with α_1 , and α_2 chosen as follows:

- $\alpha_1 = \alpha_2 = 0.7$;
- $\alpha_1 = 0.7$, $\alpha_2 = 0.7 + \epsilon$, with $\epsilon = 10^{-4}$.

Figure 6: Solution in the phase space (upper-plot) and versus time (lower-plot) for Problem (68).

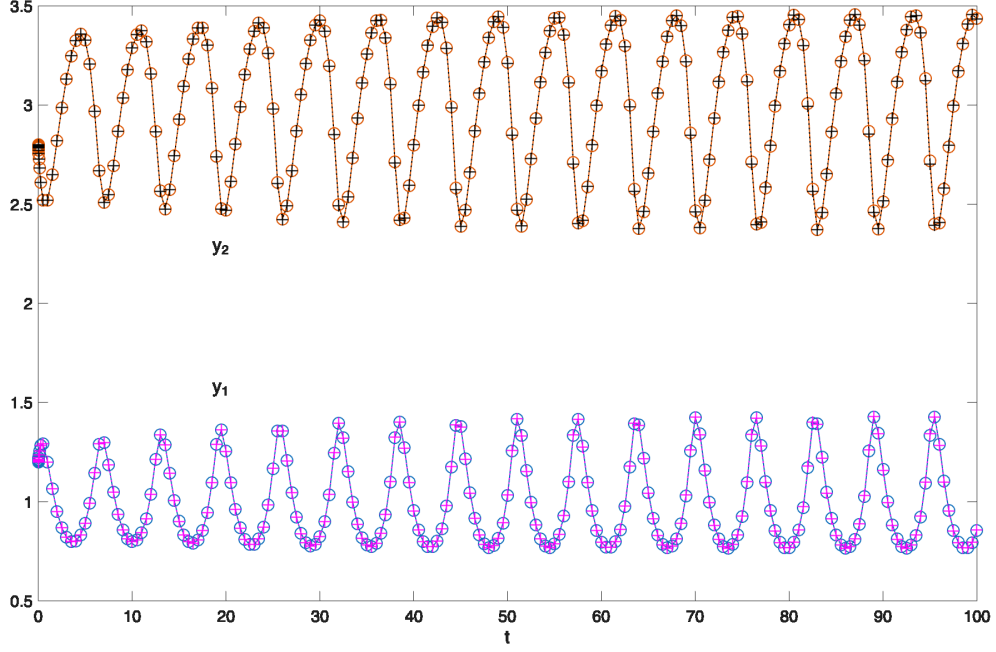

Figure 7: Solution of Problem (68), $\alpha_1 = \alpha_2 = 0.7$ (circles) and $\alpha_1 = 0.7, \alpha_2 = 0.7 + 10^{-4}$ (crosses).

As is clear, in the first case only one fractional derivative order occurs (i.e., $\nu = 1$ in (1)), whereas they are two in the second case (i.e., $\nu = 2$ in (1)). Despite this fact, the computed solutions are very similar, as is shown in Figure 7. Consequently, we shall assume that the code provides a comparable accuracy, when used with the same parameters, in both cases. In particular, similarly as done for Problem 4, we shall use the parameters $n = 1$, and $nu = 50$. Instead, the values of N vary as reported in Table 3, where we also list:

- the required number of fixed-point iterations (55) (basically, used in the initial graded mesh, where the timesteps are very small);
- the number of blended iterations (58), in the case $\nu = 1$, or simplified Newton iterations (59), in the case $\nu = 2$;
- the execution times (in sec).

As expected, the execution times, when using the blended iteration, are lower than those required by the simplified Newton iteration, despite the fact that the latter requires less steps to reach convergence (approximately 30% less). In particular, when using the blended iteration, the code is more than 3.5 times faster than when using the simplified Newton iteration.

Table 3: Execution times (in sec) and nonlinear iterations for `fhbvm2_2`, when used for solving (68) with $\alpha_1 = \alpha_2 = 0.7$ (case 1) and $\alpha_1 = 0.7, \alpha_2 = 0.7 + 10^{-4}$ (case 2).

	case 1			case 2		
N	fixed-point iterations	blended iterations	execution time	fixed-point iterations	Newton iterations	execution time
200	150	2679	0.40	142	1950	1.51
250	149	3193	0.45	141	2238	1.65
300	146	3644	0.54	146	2529	2.05
350	146	4115	0.64	146	2822	2.37
400	152	4627	0.73	144	3084	2.80
450	151	5116	0.85	143	3368	3.14
500	151	5617	0.99	143	3667	3.54
550	150	5969	1.07	150	3934	3.83
600	148	6423	1.19	148	4146	4.22

Problem 6

At last, we consider the following multi-order fractional version of the predator-prey model described in [44], including intra-species competition:

$$\begin{aligned}
y_1^{(\alpha_1)} &= r_1 y_1 - a_{11} y_1^2 - a_{12} y_1 y_2 - a_{13} y_1 y_3, \\
y_2^{(\alpha_2)} &= a_{21} y_1 y_2 - a_{22} y_2^2 - \frac{a_{23} y_2 y_3}{1 + \beta y_2} - r_2 y_2, \\
y_3^{(\alpha_2)} &= a_{31} y_1 y_3 + \frac{a_{32} y_2 y_3}{1 + \beta y_2} - a_{33} y_3^2 - r_3 y_3,
\end{aligned}
\quad t \in [0, T], \quad (69)$$

$$y(0) = y^0 \in \mathbb{R}^3.$$

Here:

- y_1 represents the density of the preys;
- y_2 is the density of the *intermediate* predators, which cannot prey the *top* predators;
- y_3 denotes the density of the *top* predators, which can prey also the *intermediate* ones.

We use the following parameters: $\alpha_1 = 0.99, \alpha_2 = 0.8; r_1 = 5, r_2 = 1, r_3 = 0.1; a_{11} = 0.01, a_{12} = 1, a_{13} = 35, a_{21} = 1, a_{22} = 0.2, a_{23} = 1, a_{31} = 0.1, a_{32} = 1, a_{33} = 0.3; \beta = 0.01$. Moreover, we use the initial point $y^0 = (0.7, 0.2, 0.1)^\top$, and integrate up to $T = 500$: as one may infer from the plots in Figure 8, the solution tends to become of periodic type, with a period $\tau \approx 11.8$. Since a reference solution is not available for this problem, to obtain corresponding accuracy results we run each code on consecutive doubled meshes, as below specified:

- `fde_pi12_pc, fde_pi12_pc-10, fde_pi2_im`: $h = 10^{-2} \cdot 2^{1-\ell}, \ell = 1, \dots, 7$;
- `fhbvm2_2`: $n = 1, nu = 50, N = 500 \cdot 2^{\ell-1}, \ell = 1, 2, 3, 4$.¹¹

¹¹Consequently, the timestep in the uniform part of the mesh is $h = 2^{1-\ell}, \ell = 1, 2, 3, 4$.

Table 4: Estimated accuracy (in mescd) and execution times when solving (69) on consecutive doubled meshes (see text for details).

ℓ	fde_pi12_pc		fde_pi12_pc-10		fde_pi2_im		fhbvm2_2	
	mescd	sec	mescd	sec	mescd	sec	mescd	sec
1	0.59	0.76	1.83	2.21	1.83	21.41	10.22	4.41
2	1.16	1.54	2.43	4.40	2.43	40.73	11.35	9.29
3	1.77	3.13	3.03	8.91	3.03	78.52	11.68	22.50
4	2.40	6.30	3.64	18.15	3.64	161.37		
5	3.09	12.12	4.22	36.71	4.22	309.53		
6	3.55	24.16	4.06	74.04	4.06	596.44		

Then, for each code, the accuracy on the ℓ th mesh is estimated through the solution on the subsequent $(\ell + 1)$ st mesh. The obtained results are listed in Table 4, from which one may conclude that:

- `fde_pi12_pc` reaches 3.5 mescd in about 24 sec;
- `fde_pi12_pc-10` and `fde_pi2_im` do have a comparable accuracy, and can reach a higher accuracy (slightly larger than 4 mescd) but with a higher execution time. Moreover, that of `fde_pi2_im` is much larger than that of `fde_pi12_pc-10`;
- `fhbvm2_2` reaches a very high accuracy (almost 12 mescd) in about 22 sec. Moreover, it is able to achieve more than 10 mescd by using a timestep as large as 1, in the uniform part of the mesh: this reflects the capability, of the underlying FHBVM(22,22) method, of obtaining a spectrally accurate solution.

8 Conclusions

In this paper, we have extended the class of methods named *Fractional HBVMs (FHBVMs)* for numerically solving multi-order FDEs. The implementation details of the methods have been given in the general case: in particular, a comprehensive review of Jacobi-Pinheiro quadratures has been presented, with the aim of providing algorithmic insights. As a result, a new Matlab[©] code, named `fhbvm2_2`, has been released. The code implements the case of 2 possible different fractional orders, and relies on FHBVM(22,22): this latter method had already been used in the code `fhbvm2`, handling the single-order case. Alike the latter code, also the new one is able to gain spectrally accurate solutions, on a suitably chosen mesh. Numerical tests taken from the literature duly confirm this fact, also showing its superior performance over existing numerical codes, designed for solving multi-order FDEs, available on the internet.

Data availability. The Matlab[©] code `fhbvm2_2` is available at the URL [56].

Acknowledgements. The first three authors are members of the “Gruppo Nazionale per il Calcolo Scientifico-Istituto Nazionale di Alta Matematica (GNCS-INdAM)”. The last author is sup-

Figure 8: Solution of Problem (69) in the phase space (upper plot) and versus time (lower plot). In the upper plot, the circle denotes the initial point of the trajectory.

ported by the project n.ro PUTJD1275 of the Estonian Research Council. The paper has been written during a period of visit of the last author at the University of Florence.

Declarations. The authors declare no conflict of interests.
