

THE LINK SURGERY MODULES OF 2-COMPONENT L-SPACE LINKS

DAREN CHEN, IAN ZEMKE, AND HUGO ZHOU

ABSTRACT. In our earlier work [CZZ24], we studied the link surgery modules of two component L-space links. Therein, we computed two of the four idempotents of such modules. In this article, we use Koszul duality to give an alternate account of this proof, and also to extend it to compute the entire link surgery modules of such links, modulo a technical result which will be proven in a subsequent paper.

1. INTRODUCTION

If L is a link in S^3 with integral framing Λ , the *link surgery complex* of L , denoted $\mathcal{C}_\Lambda(L)$, is a chain complex defined by Manolescu and Ozsváth [MO10] which computes the Heegaard Floer homology of $S^3_\Lambda(L)$.

The *link Floer complex* is an invariant of links, defined by Ozsváth and Szabó [OS08]. It takes the form of a free and finitely generated chain complex $\mathcal{CFL}(L)$ over the ring $\mathbb{F}[W_1, Z_1, \dots, W_n, Z_n]$, where $n = |L|$. Conceptually, we can think of the link surgery complex $\mathcal{C}_\Lambda(L)$ is an enhancement of the complex $\mathcal{CFL}(L)$ which incorporates some additional algebraic data necessary for the surgery formula.

In [Zem21, Zem23], the second author reinterpreted the link surgery complex as an invariant for 3-manifolds with parametrized torus boundary components (i.e. the link complement), and repackaged the surgery complex in terms of certain A_∞ -module categories over an algebra, called the *surgery algebra*, denoted \mathcal{K} . This theory was modeled on the bordered theory of Lipshitz, Ozsváth and Thurston [LOT18], and features a gluing theorem for the invariant of a manifold obtained by gluing two 3-manifolds with torus boundaries together.

To a link with 2-components $L \subseteq S^3$, the second author defines in [Zem21] an A_∞ -bimodule (more precisely, a DA -bimodule), denoted ${}_{\mathcal{K}}\mathcal{X}(L)^{\mathcal{K}}$, which encodes the link surgery complex of L . The algebraic structure of this invariant as a bimodule (as opposed to just a chain complex) allows for the gluing formulas from [Zem21].

In this article, we study the link surgery complexes and bimodules of a family of 2-component links called *L-space links*. We recall that a link $L \subseteq S^3$ is an *L-space link* if $S^3_\Lambda(L)$ is an L-space for all integral surgeries $\Lambda \gg 0$. (Recall that a rational homology 3-sphere is an *L-space* if $\text{rank}_{\mathbb{Z}/2} \widehat{HF}(Y)$ is equal to the number of elements in $H_1(Y)$).

L-space knots and links are well-studied in the literature. Ozsváth and Szabó proved in [OS05] that the knot Floer complex of an L-space knot K is a staircase complex. For example, the complex of the $(3, 4)$ torus knot is freely generated over $\mathbb{F}[W, Z]$ by five elements, $\mathbf{x}_0, \mathbf{x}_1, \mathbf{x}_2, \mathbf{x}_3$ and \mathbf{x}_4 , and has differential shown below:

$$\begin{array}{ccccc}
 & \mathbf{x}_1 & & \mathbf{x}_3 & \\
 & \swarrow \scriptstyle W & \searrow \scriptstyle Z^2 & \swarrow \scriptstyle W^2 & \searrow \scriptstyle Z \\
 \mathbf{x}_0 & \xleftarrow{\quad} & & \xleftarrow{\quad} & \mathbf{x}_4 \\
 & & \mathbf{x}_2 & &
 \end{array} \quad . \tag{1.1}$$

In [CZZ24], we extended this computation to 2-component L-space links. We proved that if L is a 2-component L-space link, then $\mathcal{CFL}(L)$ is formal, i.e., homotopy equivalent to a free-resolution of its homology.

Work of the second author with Borodzik and Liu [BLZ22] extends Ozsváth and Szabó's result in a different direction. Therein, it is proven that if L is a *plumbed* L-space link in S^3 , then $\mathcal{CFL}(L)$ is also formal. It is an open question whether non-plumbed L-space links L with more than 2-components have formal link Floer complexes.

Using work of Gorsky and Némethi [GN15], Liu [Liu17] describes a reduced model of the link surgery complex $\mathcal{C}_\Lambda(L)$ of a 2-component L-space link. This computation is sufficient for computing the Heegaard Floer homologies of surgeries on 2-component L-space links, but it is not sufficient for understanding the bimodule structure on ${}_{\mathcal{K}}\mathcal{X}(L)^{\mathcal{K}}$, which is necessary for the gluing formulas from [Zem21].

For the theorem statements in this paper, it is important also that the link surgery bimodule ${}_{\mathcal{K}}\mathcal{X}(L)^{\mathcal{K}}$ depends on an extra choice of data, called an *arc-system*. For the purpose of this introduction, an arc system is equivalent to a designation of each component of L as having either an “alpha parallel arc” or a “beta parallel arc”. (The meaning of this designation is not important for our paper).

In this paper, we study the DA -bimodules of 2-component L-space links over the surgery algebra. In [CZZ24], we gave a partial computation of these bimodules. We computed two of the four idempotents of the module ${}_{\mathcal{K}}\mathcal{X}(L)^{\mathcal{K}}$. That is, inside of \mathcal{K} there is a subalgebra $R_0 := \mathbb{F}[W, Z] \subseteq \mathcal{K}$, and we computed the corresponding bimodule with outputs restricted to this subalgebra. The main goal of this paper is to compute the entire complex (modulo some technical arguments that will appear in the subsequent [Zem]).

Before stating our theorem, we need the following technical definition:

Definition 1.1. We say that the structure maps δ_{n+1}^1 of a type- DA bimodule ${}_{\mathcal{K}}\mathcal{X}^{\mathcal{K}}$ are U -equivariant if

$$\delta_{n+1}^1(a_n, \dots, Ua_i, \dots, a_1, \mathbf{x}) = \delta_{n+1}^1(a_n, \dots, a_i, \dots, a_1, \mathbf{x}) \cdot U$$

for all $a_n, \dots, a_1 \in \mathcal{K}$ and $\mathbf{x} \in \mathcal{X}$. Here, $\cdot U$ means to multiply the \mathcal{K} factor of the output of δ_{n+1}^1 by U .

In this article, we define a candidate bimodule ${}_{\mathcal{K}}\mathcal{X}^{\text{alg}}(L)^{\mathcal{K}}$ for a 2-component L-space link $L \subseteq S^3$. This bimodule is determined by the H -function of L . By work of Gorsky and Némethi [GN15], the H -function is determined by the Alexander polynomials of L and its sublinks, so we can also view $\mathcal{X}^{\text{alg}}(L)$ as being determined by the Alexander polynomials of L and its sublinks.

Theorem 1.2. *Let $L \subseteq S^3$ be a two component L-space link. If \mathcal{A} is a choice of arc-system for L such that the bimodule ${}_{\mathcal{K}}\mathcal{X}(L; \mathcal{A})^{\mathcal{K}}$ has a model with U -equivariant structure maps, then there is a homotopy equivalence*

$${}_{\mathcal{K}}\mathcal{X}(L; \mathcal{A})^{\mathcal{K}} \simeq {}_{\mathcal{K}}\mathcal{X}^{\text{alg}}(L)^{\mathcal{K}}.$$

In a forthcoming article [Zem], the second author proves the following:

Theorem 1.3 ([Zem]). *If $L \subseteq S^3$ is a 2-component link and \mathcal{A} is an arc-system where the arc for one component of L is beta-parallel while the arc for the other component is alpha-parallel, then ${}_{\mathcal{K}}\mathcal{X}(L; \mathcal{A})^{\mathcal{K}}$ admits a U -equivariant model.*

In particular, Theorem 1.3 implies that there is an arc-system for L for which Theorem 1.2 applies.

Remark 1.4. There are arc systems on L-space links for which the structure maps on ${}_{\mathcal{K}}\mathcal{X}(L; \mathcal{A})^{\mathcal{K}}$ cannot be made U -equivariant. For example, in [Zem21, Section 16,17], the second author computed a reduced model of the bimodule ${}_{\mathcal{K}}\mathcal{X}(L; \mathcal{A})^{\mathcal{K}}$ when L was a Hopf link and \mathcal{A} consisted of two alpha-parallel arcs, and the resulting structure maps are not U -equivariant. In fact, it is not hard to see that this bimodule is not even homotopy equivalent to a U -equivariant bimodule.

2. ALGEBRAIC BACKGROUND

2.1. Type- D , A , DA and DD bimodules. In this section, we recall the algebraic framework of type- D , A and DA bimodules due to Lipshitz, Ozsváth and Thurston, as well as the natural analogs of these notions for bimodules over curved dg -algebras. We refer the reader to [LOT18] [LOT15] for further details on the uncurved setting, and we refer the reader to [OS19, Section 3] for additional background on this framework in the presence of curvature.

Let \mathbf{k} be a unital ring with characteristic 2. A *curved dg -algebra* (\mathcal{A}, μ_i) over \mathbf{k} consists of a (\mathbf{k}, \mathbf{k}) -bimodule \mathcal{A} , equipped with \mathbf{k} -linear operations

$$\mu_2: \mathcal{A} \otimes_{\mathbf{k}} \mathcal{A} \rightarrow \mathcal{A}, \quad \mu_1: \mathcal{A} \rightarrow \mathcal{A}, \quad \mu_0: \mathbf{k} \rightarrow \mathcal{A}$$

satisfying the following:

- (1) \mathcal{A} is an associative algebra with respect to μ_2 .
- (2) $\mu_1^2 = 0$, and furthermore μ_2 satisfies the Leibniz rule with respect to μ_1 : $\mu_1(a \cdot b) = \mu_1(a) \cdot b + a \cdot \mu_1(b)$. (Here $a \cdot b$ denotes $\mu_2(a, b)$).
- (3) The element $\mu_0 := \mu_0(1)$ is a cycle and is central, i.e.

$$\mu_0 \cdot a = a \cdot \mu_0 \quad \text{and} \quad \mu_1(\mu_0) = 0,$$

for all $a \in \mathcal{A}$.

If (\mathcal{A}, μ_i) is a curved dg -algebra, a right *type- D module* over \mathcal{A} , denoted $\mathcal{X}^{\mathcal{A}}$, consists of a right \mathbf{k} -module \mathcal{X} equipped with \mathbf{k} -linear map

$$\delta^1: \mathcal{X} \rightarrow \mathcal{X} \otimes \mathcal{A}$$

which satisfies

$$(\mathbb{I}_{\mathcal{X}} \otimes \mu_2) \circ (\delta^1 \otimes \mathbb{I}_{\mathcal{A}}) \circ \delta^1 + (\mathbb{I}_{\mathcal{X}} \otimes \mu_1) \circ \delta^1 + \mathbb{I}_{\mathcal{X}} \otimes \mu_0 = 0.$$

If (\mathcal{A}, μ_i) and (\mathcal{B}, ν_i) are two curved dg -algebras over \mathbf{k} and \mathbf{j} , respectively, then a *DA -bimodule* ${}_{\mathcal{A}}\mathcal{X}^{\mathcal{B}}$ over $(\mathcal{A}, \mathcal{B})$ consists of a (\mathbf{k}, \mathbf{j}) -bimodule \mathcal{X} , equipped with a collection of (\mathbf{k}, \mathbf{j}) -linear structure maps

$$\delta_{j+1}^1: \underbrace{\mathcal{A} \otimes_{\mathbf{k}} \cdots \otimes_{\mathbf{k}} \mathcal{A}}_j \otimes \mathcal{X} \rightarrow \mathcal{X} \otimes_{\mathbf{j}} \mathcal{B}$$

which satisfy the following compatibility condition. We have

$$(\mathbb{I}_{\mathcal{X}} \otimes \mu_2) \circ (\delta_1^1 \otimes \mathbb{I}_{\mathcal{A}}) \circ \delta_1^1 + (\mathbb{I}_{\mathcal{X}} \otimes \mu_1) \circ \delta_1^1 + \mathbb{I}_{\mathcal{X}} \otimes \mu_0 = 0.$$

Furthermore, for each $n \geq 1$ and each $a_n, \dots, a_1 \in \mathcal{A}$ and $\mathbf{x} \in \mathcal{X}$, we have

$$\begin{aligned} 0 &= \sum (\mathbb{I}_{\mathcal{X}} \otimes \nu_2) (\delta_{n-j+1}^1 \otimes \mathbb{I}_{\mathcal{B}}) (a_n, \dots, a_{j+1}, \delta_{j+1}^1(a_j, \dots, a_1, \mathbf{x})) \\ &\quad + \sum \delta_{n-i+2}^1(a_n, \dots, \mu_i(a_{j+i-1}, \dots, a_j), \dots, a_1, \mathbf{x}) \\ &\quad + (\mathbb{I}_{\mathcal{X}} \otimes \nu_1) (\delta_{n+1}^1(a_n, \dots, a_1, \mathbf{x})). \end{aligned}$$

Finally, we discuss *DD -bimodules*. If \mathcal{A} and \mathcal{B} are curved dg -algebras over \mathbf{j} and \mathbf{k} , respectively, a *DD -bimodule* ${}^{\mathcal{A}}\mathcal{X}^{\mathcal{B}}$ consists of a (\mathbf{j}, \mathbf{k}) -bimodule \mathcal{X} , equipped with a structure map

$$\delta^{1,1}: \mathcal{X} \rightarrow \mathcal{A} \otimes_{\mathbf{j}} \mathcal{X} \otimes_{\mathbf{k}} \mathcal{B}.$$

The compatibility condition is the same as if we view $\delta^{1,1}$ as a map from \mathcal{X} to $\mathcal{X} \otimes_{\mathbf{j}^{\text{opp}} \otimes \mathbf{k}} (\mathcal{A}^{\text{opp}} \otimes_{\mathbb{F}} \mathcal{B})$, and view \mathcal{X} as a type- D structure over $\mathcal{A}^{\text{opp}} \otimes_{\mathbb{F}} \mathcal{B}$. Here, \mathcal{A}^{opp} denotes

the curved dg algebra with underlying space \mathcal{A} , but with $\mu_2^{\text{opp}}(a_1, a_2) = \mu_2(a_2, a_1)$ (and the same differential and curvature). The tensor product $\mathcal{A}^{\text{opp}} \otimes_{\mathbb{F}} \mathcal{B}$ is equipped with the curvature $\mu_0 \otimes 1 + 1 \otimes \mu_0$, and with the differential $\mu_1 \otimes \text{id} + \text{id} \otimes \mu_1$.

2.2. A perturbation lemma. In this section we prove a simple perturbation lemma, which will be useful later. We recall that a dg -category is a category where the morphism sets are chain complexes of abelian groups, and whose differential satisfies the Leibniz rule with respect to composition. For our purposes, we will only consider the case where the morphism sets have characteristic 2, so that the differential satisfies

$$\partial(g \circ f) = \partial(g) \circ f + g \circ \partial(f).$$

If \mathcal{C} is a dg -category, a *twisted complex* in \mathcal{C} consists of a pair $\text{Tw}_{\alpha}(X) := (X, \alpha)$ where X is an object of \mathcal{C} and $\alpha \in \text{Hom}_{\mathcal{C}}(X, X)$ is a morphism satisfying the Mauer-Cartan relation:

$$\partial(\alpha) + \alpha \circ \alpha = 0.$$

The set of twisted complexes forms a category. If $\text{Tw}_{\alpha}(X)$ and $\text{Tw}_{\beta}(Y)$ are twisted complexes, we define

$$\text{Hom}_{\text{Tw}(\mathcal{C})}(\text{Tw}_{\alpha}(X), \text{Tw}_{\beta}(Y)) := \text{Hom}_{\mathcal{C}}(X, Y),$$

with differential

$$\partial_{\text{Tw}(\mathcal{C})}(f) = \partial_{\mathcal{C}}(f) + \beta \circ f + f \circ \alpha.$$

It is easy to check that $\text{Tw}(\mathcal{C})$ is a dg -category. (Compare [Sei08, Section 1.5]).

The categories of interest to us (chain complexes, type- D modules, A_{∞} -modules, etc.) are all closed under twists, in the sense that there is a canonical functor from $\text{Tw}(\mathcal{C})$ to \mathcal{C} . For example, in the category of chain complexes, this functor sends $\text{Tw}_{\alpha}(X, d)$ to $(X, d + \alpha)$. Similarly for the dg -categories consisting of type- D and type- DA bimodules over dg -algebras, the twisted complex $\text{Tw}_{\alpha}((X, \delta_{j+1}^1))$ is sent to $(X, \alpha_{j+1}^1 + \delta_{j+1}^1)$. Because of this, we typically conflate $\text{Tw}_{\alpha}(X) \in \text{Tw}(\mathcal{C})$ and its image in \mathcal{C} .

Lemma 2.1. *Suppose that X is an object of a dg category and $h \in \text{End}(X)$ is an endomorphism such that $1 + h$ is invertible. Then $\alpha = \partial(h)(1 + h)^{-1}$ is a Mauer-Cartan element and X is isomorphic to $\text{Tw}_{\alpha}(X)$.*

Proof. To see that α is a Mauer-Cartan element, we observe that

$$\partial(\alpha) + \alpha^2 = \partial(h)\partial((1 + h)^{-1}) + \partial(h)(1 + h)^{-1}\partial(h)(1 + h)^{-1}.$$

This is zero if and only if

$$\partial(h)\partial((1 + h)^{-1})(1 + h) + \partial(h)(1 + h)^{-1}\partial(h)$$

is zero. We note that $\partial((1 + h)^{-1})(1 + h) = (1 + h)^{-1}\partial(1 + h) = (1 + h)^{-1}\partial(h)$, and hence the above equation vanishes.

We now define a morphism f from X to $\text{Tw}_{\alpha}(X)$ to be $1 + h$. By definition, the twisted morphism differential of f is equal to

$$\partial(f) + \alpha \circ f,$$

(where $\partial(f)$ is the differential of f when viewed as an endomorphism of X). With our choice of α , we observe that the above is equal to

$$\partial(h) + \partial(h)(1 + h)^{-1}(1 + h) = 0,$$

so f is a cycle with respect to the differential on morphisms of twisted complexes. Similarly, we can define a morphism $g = (1 + h)^{-1}$ from $\text{Tw}_\alpha(X)$ to X and it is straightforward to verify that g is a cycle as well. We observe that f and g are inverses, so the claim is proven. \square

Remark 2.2. Our typical usage of the above lemma is as follows. We will consider a DD -bimodule ${}^{\mathcal{A}}\mathcal{X}^{\mathcal{B}}$ with differential $\delta^{1,1}$. We will want to perturb the structure map $\delta^{1,1}$ by adding a term $\partial(h)$ to it in order to simplify some terms of the differential. In general, this will not be possible because $\partial(h)$ is not typically a Maurer-Cartan element. However, $\partial(h)(1 + h)^{-1}$ is a Maurer-Cartan element (as demonstrated in the previous lemma). Furthermore, in the cases of interest to us, the infinite sum $(1 + h)^{-1} = \sum_{n=0}^{\infty} h^n$ makes sense, and furthermore we view $\alpha = \sum_{n=0}^{\infty} \partial(h)h^n$ as coinciding with $\partial(h)$ up to first approximation.

3. HEEGAARD FLOER BACKGROUND

3.1. Knot and link Floer homology. We recall some basics about knot and link Floer homology. Knot Floer homology is an invariant of knots due independently to Ozsváth and Szabó [OS04] and Rasmussen [Ras03]. Link Floer homology is an invariant of links due to Ozsváth and Szabó.

To a knot $K \subseteq Y$, the invariant takes the form of a free and finitely generated chain complex $\mathcal{CFK}(Y, K)$ over $\mathbb{F}[W, Z]$, where $\mathbb{F} = \mathbb{Z}/2$. We are primarily interested in the case that $Y = S^3$, in which case we write $\mathcal{CFK}(K)$ for the invariant. There are three gradings of interest, denoted $\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}}$ and A , which are related by the equation

$$A = \frac{1}{2}(\text{gr}_{\mathbf{w}} - \text{gr}_{\mathbf{z}}).$$

The algebra $\mathbb{F}[W, Z]$ is graded by

$$(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}}, A)(W) = (-2, 0, -1), \quad \text{and} \quad (\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}}, A)(Z) = (0, -2, 1).$$

It is convenient to write

$$U := WZ.$$

If $L \subseteq S^3$ is a link, the invariant $\mathcal{FLO}(L)$ takes the form of a free, finitely generated chain complex over the ring $\mathbb{F}[W_1, \dots, W_n, Z_1, \dots, Z_n]$. This invariant has a more complicated set of gradings. We write

$$\mathbb{H}(L) = \prod_{i=1}^n \left(\mathbb{Z} + \frac{\text{lk}(K_i, L \setminus K_i)}{2} \right).$$

There is an Alexander grading $A = (A_1, \dots, A_n)$ which takes values in $\mathbb{H}(L)$. The variables have gradings

$$A_i(Z_j) = -A_i(W_j) = \delta_{ij},$$

where δ_{ij} is the Kronecker delta.

Similar to the case of knots, it is convenient to write $U_i = W_i Z_i$. All of the U_i induce chain homotopic actions on homology. See, for example, [BLZ24, Equation 2.8].

As before, there are Maslov gradings $\text{gr}_{\mathbf{w}}$ and $\text{gr}_{\mathbf{z}}$, though in fact there is a more refined collection of Maslov gradings. If \mathfrak{o} is any orientation on L , then there is a Maslov grading $\text{gr}_{\mathfrak{o}}$ on $\mathcal{FLO}(L)$. The construction of $\mathcal{FLO}(L)$ requires a choice of base

orientation, which we will denote \mathfrak{o}_0 . The Maslov grading $\text{gr}_{\mathfrak{o}_0}$ coincides with $\text{gr}_{\mathbf{w}}$, and more generally $\text{gr}_{\mathfrak{o}}$ satisfies

$$\text{gr}_{\mathfrak{o}}(W_i) = \begin{cases} -2 & \text{if } \mathfrak{o}|_{K_i} = \mathfrak{o}_0|_{K_i}, \\ 0 & \text{if } \mathfrak{o}|_{K_i} = -\mathfrak{o}_0|_{K_i}. \end{cases}$$

Similarly

$$\text{gr}_{\mathfrak{o}}(Z_i) = \begin{cases} 0 & \text{if } \mathfrak{o}|_{K_i} = \mathfrak{o}_0|_{K_i}, \\ -2 & \text{if } \mathfrak{o}|_{K_i} = -\mathfrak{o}_0|_{K_i}. \end{cases}$$

We have the following relation:

$$\text{gr}_{\mathfrak{o}_0} - \text{gr}_{\mathfrak{o}} = \left(\sum_{\mathfrak{o}|_{K_i} = -\mathfrak{o}_0|_{K_i}} 2A_i \right) - \text{lk}(L_{\mathfrak{o}}, L \setminus L_{\mathfrak{o}}),$$

where $L_{\mathfrak{o}}$ is the set of components of L where \mathfrak{o} differs from \mathfrak{o}_0 . In computing the above linking number, we orient L as in \mathfrak{o}_0 . See [Zem21, Lemma 6.4].

3.2. L-space knots and links. An important class of knots and links are *L-space links*. A link L is called an *L-space link* if $S_{\Lambda}^3(L)$ is a Heegaard Floer L-space for all integral framings $\Lambda \gg 0$. (Recall that a rational homology 3-sphere is an *L-space* if $HF^-(Y)$ is isomorphic to $\bigoplus_{|H_1(Y)|} \mathbb{F}[U]$, where $|H_1(Y)|$ is the number of elements in $H_1(Y)$). Using the large surgeries formula of Manolescu and Ozsváth [MO10, Theorem 12.1], an equivalent condition for L to be an L-space link is that the module $\mathcal{HFL}(L)$ is free as an $\mathbb{F}[U]$ module, where U acts by any of the $U_i = W_i Z_i$ (all U_i have the same action on homology). Equivalently, L is an L-space link if and only

$$\mathcal{HFL}(L) \cong \bigoplus_{\mathbf{s} \in \mathbb{H}(L)} \mathbb{F}[U].$$

When K is an L-space knot, the knot Floer homology group $\mathcal{HFL}(L)$ has rank 0 or rank 1 in each $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ -grading. Furthermore, it is not hard to see that $\text{gr}_{\mathbf{w}}(\mathbf{x}) \leq 0$ and $\text{gr}_{\mathbf{z}}(\mathbf{x}) \leq 0$ for any non-zero, homogeneously graded element $\mathbf{x} \in \mathcal{HFL}(L)$. Therefore, $\mathcal{HFL}(L)$ can be naturally embedded inside of $\mathbb{F}[W, Z]$ as a monomial ideal (an ideal spanned by monomials). We illustrate the link Floer homology of the $(3, 4)$ -torus knot, $\mathcal{HFL}(T_{3,4})$, in Figure 3.1.

FIGURE 3.1. The link Floer complex $\mathcal{CFK}(T_{3,4})$ (left) and its homology $\mathcal{HFK}(T_{3,4})$ (right). Each shaded square on the right denotes a generator over \mathbb{F} . Multiplication by W shifts to the right, while multiplication by Z shifts upwards. We can view the entire upper-right quadrant as $\mathbb{F}[W, Z]$.

3.3. The link surgery complex. To a link $L \subseteq S^3$ with integral framing Λ , Manolescu and Ozsváth [MO10] describe a chain complex $\mathcal{C}_\Lambda(L)$. The chain complex is a module over $\mathbb{F}[[U_1, \dots, U_n]]$, where $n = |L|$. The homology of $\mathcal{C}_\Lambda(L)$ is isomorphic to the completion of the Heegaard Floer homology with respect to (U) :

$$H_*(\mathcal{C}_\Lambda(L)) \cong \mathbf{HF}^-(S_\Lambda^3(L)) := HF^-(S_\Lambda^3) \otimes_{\mathbb{F}[U]} \mathbb{F}[[U]].$$

Work of the second author [Zem23] extends this theory to arbitrary Morse framed links in 3-manifolds.

We now sketch some properties of the link surgery complex, focusing on links in S^3 . We refer the reader to [MO10] or [Zem23] for further details. The link surgery complex $\mathcal{C}_\Lambda(L)$ is a hypercube of chain complexes (see [MO10, Section 5] for background on this algebraic formalism). In more detail, the underlying group of $\mathcal{C}_\Lambda(L)$ decomposes as a direct sum

$$\mathcal{C}_\Lambda(L) \cong \bigoplus_{\varepsilon \in \{0,1\}^n} \mathcal{C}_\varepsilon.$$

Furthermore, the differential D on $\mathcal{C}_\Lambda(L)$ decomposes as a sum

$$D = \sum_{\varepsilon \leq \varepsilon'} D_{\varepsilon, \varepsilon'},$$

where $D_{\varepsilon, \varepsilon'}$ maps \mathcal{C}_ε to $\mathcal{C}_{\varepsilon'}$.

The complex $\mathcal{C}_{\vec{0}}$ is isomorphic to a completion of $\mathcal{CFL}(L)$. More generally, there is a homotopy equivalence

$$\mathcal{C}_\varepsilon \simeq \mathcal{CFL}(L_\varepsilon, \mathbf{p}_\varepsilon) \otimes_{\mathbb{F}} \mathbb{F}[T_{i_1}, T_{i_1}^{-1}, \dots, T_{i_k}, T_{i_k}^{-1}]. \quad (3.1)$$

In the above, $L_\varepsilon \subseteq L$ is the sublink of components $K_i \subseteq L$ where $\varepsilon_i = 0$, and $\{i_1, \dots, i_k\} = \varepsilon^{-1}(1)$. Also \mathbf{p}_ε is a collection of $n - |L_\varepsilon|$ extra basepoints, which are disjoint from L_ε .

The differential $D_{\varepsilon, \varepsilon'}$ decomposes further as a sum. Write

$$M_{\varepsilon, \varepsilon'} := L_\varepsilon \setminus L_{\varepsilon'}.$$

The components of $M_{\varepsilon, \varepsilon'}$ are in one-to-one correspondence with the set of indices which are increased in ε' from ε . The differential decomposes over the set of orientations of $M_{\varepsilon, \varepsilon'}$, for which we write $\mathfrak{o}(M_{\varepsilon, \varepsilon'})$. If \mathfrak{o} is an orientation, write $M_{\varepsilon, \varepsilon'}^\mathfrak{o}$ for $M_{\varepsilon, \varepsilon'}$, equipped with this orientation. Following standard conventions, we write $\vec{M}_{\varepsilon, \varepsilon'}$ for a sublink of L , equipped with a choice of orientation. The map $D_{\varepsilon, \varepsilon'}$ decomposes as a sum

$$D_{\varepsilon, \varepsilon'} = \sum_{\mathfrak{o}(M_{\varepsilon, \varepsilon'})} \Phi_{\varepsilon, \varepsilon'}^{M_{\varepsilon, \varepsilon'}^\mathfrak{o}},$$

where the sum is over the set of orientations on M . We frequently omit the subscripts and write just $\Phi^{\vec{M}}$, when \vec{M} is an oriented sublink of L .

Following standard conventions, we identify a base orientation on L , and say that other orientations are obtained by reversing components relative to this base orientation.

Given a base orientation on L , we obtain a $\mathbb{H}(L)$ -valued Alexander grading on $\mathcal{CFL}(L)$, and consequently on $\mathcal{C}_{\vec{0}}$. If ε is an arbitrary index, then Equation (3.1) gives a $\mathbb{H}(L_\varepsilon)$ -valued Alexander grading on \mathcal{C}_ε . We extend this to an Alexander grading taking values in $\mathbb{H}(L_\varepsilon) \times \mathbb{Z}^{n-|L_\varepsilon|}$, by declaring $A_j(T_i^{\pm 1})$ to be $\pm \delta_{ij}$ (the Kronecker delta). Note

that the $\mathbb{Z}^{n-|L_\varepsilon|}$ components are only well-defined up to an overall shift, though the $\mathbb{H}(L_\varepsilon)$ component of the grading is uniquely determined. Abusing notation slightly, we will write $A = (A_1, \dots, A_n)$ also for this extension of the Alexander grading. See [Zem23, Section 7.2] for a similar discussion.

There is another natural normalization of the Alexander grading, for which we write A^σ and refer to as the σ -normalized Alexander grading. This grading takes values in $\mathbb{H}(L)$. It is determined by the property that A^σ coincides with $A^{\vec{0}}$ on $\mathcal{C}_{\vec{0}} \cong \mathcal{CFL}(L)$ and that the maps $\Phi^{\vec{M}}$ preserve A^σ whenever $\vec{M} \subseteq L$ has only positively oriented components.

If \vec{M} is an oriented sublink of L , then

$$A_i^\sigma(\Phi^{\vec{M}}) = \frac{\text{lk}(K_i, M) - \text{lk}(K_i, \vec{M})}{2}.$$

The quantity on the right can be reinterpreted as the sum over $-\text{lk}(K_i, \vec{J})$, ranging over components \vec{J} of \vec{M} which are oriented negatively relative to the base orientation on L . (See [MO10, pg. 5]).

Lemma 3.1. *There is a choice of absolute lift of the grading A , described above, which is given on \mathcal{C}_ε by the formula*

$$A_i = A_i^\sigma + \begin{cases} \text{lk}(K_i, L \setminus L_\varepsilon)/2 & \text{if } \varepsilon_i = 0 \\ \text{lk}(K_i, L \setminus K_i)/2 & \text{if } \varepsilon_i = 1. \end{cases}$$

Proof. There are two non-trivial claims. The first is that if $\varepsilon_i = 0$, then A_i agrees with the absolute Alexander grading from $\mathcal{CFL}(L_\varepsilon)$. The second is that if $\varepsilon_i = 1$, then A_i takes values in \mathbb{Z} .

The second claim, i.e., that if $\varepsilon_i = 1$ then A_i takes values in \mathbb{Z} is straightforward, as A_i^σ takes values in $\text{lk}(K_i, L \setminus K_i)/2 + \mathbb{Z}$ by definition. Therefore we focus on the first claim.

The first claim is clear if $\varepsilon = \vec{0}$. We prove the claim by induction on ε and i . Assume that it is true for some ε and index i such that $\varepsilon_i = 0$ and $\varepsilon' = \varepsilon + e_j$, for some $j \neq i$. The shift in the statement changes by

$$\frac{\text{lk}(K_i, L \setminus (L_\varepsilon \cup K_j))}{2} - \frac{\text{lk}(K_i, L \setminus L_\varepsilon)}{2} = -\frac{\text{lk}(K_i, K_j)}{2}.$$

On the other hand, this is exactly the shift in the absolute Alexander grading A_i under the map Φ^{+K_j} by [Zem21, Lemma 6.4 (4)]. (Implicitly, we are here using the fact that Φ^{K_j} can be described as the composition of the map which localizes at Z_j , followed by the composition of a grading preserving homotopy equivalence which sets $U_j = W_j Z_j$ and $Z_j = T_j$). This completes the proof. \square

Using the above shifts, it is easy to verify that if $L_{\varepsilon'} = L_\varepsilon \sqcup M$, then

$$A_i(\Phi_{\varepsilon, \varepsilon'}^{\vec{M}}) = \frac{1}{2} \cdot \begin{cases} -\text{lk}(K_i, \vec{M}) & \text{if } \varepsilon_i = \varepsilon'_i = 0 \\ -\text{lk}(K_i, L_\varepsilon \setminus K_i) + \text{lk}(K_i, M) - \text{lk}(K_i, \vec{M}) & \text{if } \varepsilon_i = 0, \varepsilon'_i = 1 \\ \text{lk}(K_i, M) - \text{lk}(K_i, \vec{M}) & \text{if } \varepsilon_i = \varepsilon'_i = 1. \end{cases} \quad (3.2)$$

Remark 3.2. The formula for the grading shift of $\Phi^{\vec{M}}$ with respect to A^σ is simpler than with respect to A . However, the grading A is simpler to write down on \mathcal{C}_ε , since it is induced by the absolute Alexander grading on $\mathcal{CFL}(L_\varepsilon)$.

3.4. The surgery algebra \mathcal{K} . We now recall the surgery algebra from [Zem21, Zem23]. We write $\mathbf{I} = \mathbf{I}_0 \oplus \mathbf{I}_1$ for an idempotent ring on two idempotents, where each $\mathbf{I}_\varepsilon \cong \mathbb{F} = \mathbb{Z}/2$. The surgery algebra \mathcal{K} is defined as follows. We set

$$\mathbf{I}_0 \cdot \mathcal{K} \cdot \mathbf{I}_0 = \mathbb{F}[W, Z], \quad \mathbf{I}_1 \cdot \mathcal{K} \cdot \mathbf{I}_1 = \mathbb{F}[U, T, T^{-1}], \quad \mathbf{I}_0 \cdot \mathcal{K} \cdot \mathbf{I}_1 = 0.$$

We declare

$$\mathbf{I}_1 \cdot \mathcal{K} \cdot \mathbf{I}_0 = \mathbb{F}[U, T, T^{-1}] \otimes_{\mathbb{F}} \langle \sigma, \tau \rangle.$$

The generators σ and τ satisfy

$$\sigma \cdot W^i Z^j = U^i T^{j-i} \cdot \sigma \quad \text{and} \quad \tau \cdot W^i Z^j = U^j T^{j-i} \cdot \tau.$$

It is sometimes helpful to also describe two algebra morphisms

$$\phi^\sigma, \phi^\tau: \mathbb{F}[W, Z] \rightarrow \mathbb{F}[U, T, T^{-1}] \tag{3.3}$$

given by the formulas

$$\phi^\sigma(W^i Z^j) = U^i T^{j-i} \quad \text{and} \quad \phi^\tau(W^i Z^j) = U^j T^{j-i}.$$

We can restate the definitions of ϕ^σ and ϕ^τ in terms of these maps as

$$\sigma \cdot a = \phi^\sigma(a) \cdot \sigma \quad \text{and} \quad \tau \cdot a = \phi^\tau(a) \cdot \tau.$$

It is helpful to write

$$\mathcal{R}_0 := \mathbf{I}_0 \cdot \mathcal{K} \cdot \mathbf{I}_0 \quad \text{and} \quad \mathcal{R}_1 := \mathbf{I}_1 \cdot \mathcal{K} \cdot \mathbf{I}_1.$$

3.5. The Koszul dual algebra \mathcal{K}^\dagger . We now recall the Koszul dual algebra \mathcal{K}^\dagger , described by the second author in [Zem25]. Similar to \mathcal{K} , this \mathcal{K}^\dagger is an algebra over the idempotent ring $\mathbf{I} = \mathbf{I}_0 \oplus \mathbf{I}_1$. In contrast to \mathcal{K} , \mathcal{K}^\dagger is a curved dg -algebra.

We declare

$$\mathbf{I}_0 \cdot \mathcal{K}^\dagger \cdot \mathbf{I}_0 = \frac{\mathbb{F}\langle w, z, \theta \rangle}{w^2 = z^2 = [w, \theta] = [z, \theta] = \theta^2 = 0}.$$

In the above, $\mathbb{F}\langle w, z, \theta \rangle$ denotes the free, noncommutative algebra on the symbols w, z and θ .

We declare $\mathbf{I}_1 \cdot \mathcal{K}^\dagger \cdot \mathbf{I}_0 = 0$.

Next, we set

$$\mathbf{I}_1 \cdot \mathcal{K}^\dagger \cdot \mathbf{I}_1 = \frac{\mathbb{F}\langle \varphi_+, \varphi_-, \theta \rangle}{\varphi_+^2 = \varphi_-^2 = [\theta, \varphi_\pm] = \theta^2 = 0}.$$

We define $\mathbf{I}_0 \cdot \mathcal{K}^\dagger \cdot \mathbf{I}_1$ to be generated as a bimodule over $(\mathbf{I}_0 \cdot \mathcal{K}^\dagger \cdot \mathbf{I}_0, \mathbf{I}_1 \cdot \mathcal{K}^\dagger \cdot \mathbf{I}_1)$ by two algebra elements s and t . We define the product of two monomials to either be zero or be given by concatenation, subject to the following relations:

$$ws = s\varphi_- = 0, \quad zt = t\varphi_+ = 0, \quad s\theta = \theta s, \quad zs = s\varphi_+, \quad t\theta = \theta t, \quad \text{and} \quad wt = t\varphi_-.$$

As a vector space, we have

$$\mathbf{I}_0 \cdot \mathcal{K}^\dagger \cdot \mathbf{I}_1 = \text{Span}_{\mathbb{F}}(s, s\theta, zs, zs\theta, t, t\theta, wt, wt\theta).$$

Additionally, the algebra \mathcal{K}^\dagger has a differential μ_1 , which is supported only in idempotent $(0, 0)$, and which is given by

$$\mu_1(\theta) = wz + zw,$$

extended to other monomials via the Leibniz rule. Finally, \mathcal{K}^\dagger has a curvature term, supported in idempotent $(1, 1)$, given by

$$\mu_0 = \varphi_- \varphi_+ + \varphi_+ \varphi_-.$$

It is convenient to write

$$\mathcal{R}_0^\dagger := \mathbf{I}_0 \cdot \mathcal{K}^\dagger \cdot \mathbf{I}_0 \quad \text{and} \quad \mathcal{R}_1^\dagger := \mathbf{I}_1 \cdot \mathcal{K}^\dagger \cdot \mathbf{I}_1.$$

In [Zem25], the second author constructs rank 1 dualizing bimodules $\mathcal{K}^\dagger[\mathcal{C}o]^\mathcal{K}$ and $\mathcal{K}[\mathcal{T}r]_{\mathcal{K}^\dagger}$, which give equivalences of categories between suitable categories of modules over \mathcal{K} and over \mathcal{K}^\dagger . The bimodule $\mathcal{K}^\dagger[\mathcal{C}o]^\mathcal{K}$ is given by the following diagram:

$$\begin{array}{ccc} & \theta|U & \\ & \downarrow & \\ w|W & \xrightarrow{\quad} i_0 & \xleftarrow{\quad} z|Z \\ & \uparrow & \\ & t|\tau & s|\sigma \\ & \downarrow & \downarrow \\ \varphi_-|T^{-1} & \xrightarrow{\quad} i_1 & \xleftarrow{\quad} \varphi_+|T \\ & \uparrow & \\ & \theta|U & \end{array}$$

The bimodule $\mathcal{K}[\mathcal{T}r]_{\mathcal{K}^\dagger}$ is more complicated, and more details can be found in [Zem25].

We will define the *tensor weight* (or just *weight*) of a monomial in \mathcal{K}^\dagger to be the number of letters. For example

$$\text{wt}(wzw) = 3 \quad \text{wt}(s) = 1 \quad \text{wt}(wzwsz\theta) = 5.$$

It is convenient to complete \mathcal{K}^\dagger over the weight filtration. For our purposes, it is actually more convenient to complete just \mathcal{R}_0^\dagger under this weight filtration. We write \mathcal{K}^\dagger for the algebra with \mathcal{R}_0^\dagger completed in this manner. We write

$$\mathcal{R}_0^\dagger := \mathbf{I}_0 \cdot \mathcal{K}^\dagger \cdot \mathbf{I}_0.$$

Remark 3.3. Given a type- A module ${}_{\mathcal{K}}\mathcal{X}$, one can tensor with the cotrace bimodule $\mathcal{K}^\dagger[\mathcal{C}o]^\mathcal{K}$ to obtain a type- D module $\mathcal{K}^\dagger\mathcal{X}$. The reader should think of the structure map δ^1 on $\mathcal{K}^\dagger\mathcal{X}$ as encoding the following information. The w weighted component of δ^1 encodes the map $m_2(W, -)$. The θ -weighted component encodes $m_2(U, -)$. More generally, if $a \in \mathcal{K}^\dagger$ is a monomial in \mathcal{K}^\dagger with tensor weight n , then the a component of δ^1 is equal to the sum of $m_{n+1}(a_1^\dagger, \dots, a_n^\dagger, -)$, ranging over all sequences $a_n, \dots, a_1 \in \{w, z, \theta, t, \tau, \varphi_-, \varphi_+\}$ such that $a_n \cdots a_1 = a$. Here $a_i^\dagger \in \mathcal{R}_0$ denotes the dual element to $a_i \in \mathcal{R}_0^\dagger$. (E.g. if $a_i = w$ then $a_i^\dagger = W$, and so forth). We think of the type- D structure $\mathcal{K}^\dagger\mathcal{X}$ as encoding just a small collection of the actions of the A_∞ -module ${}_{\mathcal{K}}\mathcal{X}$, from which the entire module ${}_{\mathcal{K}}\mathcal{X}$ can be recovered up to homotopy equivalence.

As discussed in the introduction, the following definition is important for our purposes:

Definition 3.4.

- (1) If ${}_{\mathcal{K}}\mathcal{X}^{\mathcal{K}}$ is a DA -bimodule, we say that \mathcal{X} is U -equivariant if the structure maps satisfy

$$\delta_{n+1}^1(a_n, \dots, Ua_i, \dots, a_1, \mathbf{x}) = \delta_{n+1}^1(a_n, \dots, a_1, \mathbf{x}) \cdot U,$$

where $\cdot U$ means to multiply the \mathcal{K} factor of $\delta_{n+1}^1(a_n, \dots, a_1, \mathbf{x})$ by U . A morphism of DA -bimodules is called U -equivariant if the analogous condition is satisfied.

- (2) If ${}^{\mathcal{K}^!}\mathcal{X}^{\mathcal{K}}$ is a DD -bimodule, we say that \mathcal{X} is U -equivariant if the structure map $\delta^{1,1}$ has a component of the form $\theta \otimes \text{id} \otimes U$ (i.e. a self arrow on each generator weighted by $\theta|U$), and has no other components weighted by a multiple of θ . We say a morphism of DD -bimodules over $(\mathcal{K}^!, \mathcal{K})$ is U -equivariant if there are no components weighted by a multiple of θ .

It is straightforward to see that if ${}_{\mathcal{K}}\mathcal{X}^{\mathcal{K}}$ has U -equivariant structure maps and is strictly unital, then ${}^{\mathcal{K}^!}[\mathcal{T}r]^{\mathcal{K}} \boxtimes {}_{\mathcal{K}}\mathcal{X}^{\mathcal{K}}$ also has U -equivariant structure maps. Similarly, if f_*^1 is a strictly unital and U -equivariant morphism of DA -bimodules, then $\mathbb{I}_{[\omega]} \boxtimes f_*^1$ has no θ -weighted terms, and hence is U -equivariant in the above sense.

Slightly less obviously, it is also the case that if ${}^{\mathcal{K}^!}\mathcal{Y}^{\mathcal{K}}$ has U -equivariant structure maps (in the above sense), then ${}_{\mathcal{K}}[\mathcal{T}r]_{\mathcal{K}^!} \boxtimes {}^{\mathcal{K}^!}\mathcal{Y}^{\mathcal{K}}$ is strictly unital and has U -equivariant structure maps. See [Zem25, Corollary 5.8].

4. STAIRCASE COMPLEXES

An important component of the proofs from [CZZ24] was an analysis of staircase complexes, as well as morphisms between staircase complexes.

Definition 4.1. A *staircase complex* \mathcal{C} is a free chain complex over $\mathbb{F}[W, Z]$ with generators $\mathbf{x}_0, \mathbf{x}_1, \dots, \mathbf{x}_{2n}$ such that $\partial(\mathbf{x}_{2i}) = 0$ and

$$\partial(\mathbf{x}_{2i+1}) = \mathbf{x}_{2i}W^{\alpha_i} + \mathbf{x}_{2i+2}Z^{\beta_i},$$

for some $\alpha_i, \beta_i > 0$.

If $\mathcal{C} = (\partial: \mathcal{C}_1 \rightarrow \mathcal{C}_0)$ is a staircase complex, we define the *algebraic grading* on \mathcal{C} to be 1 on \mathcal{C}_1 and 0 on \mathcal{C}_0 .

Another perspective on staircase complexes is that they are free-resolutions of their homology. That is, if $\mathcal{C} = (\partial: \mathcal{C}_1 \rightarrow \mathcal{C}_0)$ is a staircase complex, then the following sequence is exact:

$$0 \longrightarrow \mathcal{C}_0 \xrightarrow{\partial} \mathcal{C}_1 \longrightarrow H_*(\mathcal{C}) \longrightarrow 0.$$

Lemma 4.2. Suppose that \mathcal{A} and \mathcal{B} are two staircase complexes and $F: H_*(\mathcal{A}) \rightarrow H_*(\mathcal{B})$ is a homogeneously graded $\mathbb{F}[W, Z]$ -equivariant map. Then there is a chain map $f: \mathcal{A} \rightarrow \mathcal{B}$ which induces F on homology and preserves the algebraic grading. Furthermore, the map f is unique up to chain homotopy. In particular, if $f, g: \mathcal{A} \rightarrow \mathcal{B}$ are two homogeneously graded maps which preserve the algebraic grading and which induce the same map on homology, then f and g are chain homotopic.

Since \mathcal{A} and \mathcal{B} are free resolutions of their homology, the above result follows from basic homological algebra. (See [Wei94, Theorem 2.2.6]).

We will have use for some slightly less obvious results about staircase complexes:

Lemma 4.3 ([CZZ24, Lemma 5.19]). *If \mathcal{S} is a staircase complex and $f: \mathcal{S} \rightarrow \mathcal{S}$ is a chain map which shifts the $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ -grading by $(-1, -1)$, then f is null-homotopic.*

Remark 4.4. If we write $\mathcal{S} = \text{Cone}(\partial: \mathcal{S}_1 \rightarrow \mathcal{S}_0)$, then an endomorphism ϕ of \mathcal{S} with $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})(\phi) = (-1, -1)$ can be written as a sum $\phi = \phi_{10} + \phi_{01}$ where ϕ_{ij} maps \mathcal{S}_j to \mathcal{S}_i . If ϕ is a chain map, then it is easy to see that $\phi_{10} = 0$, because ∂ is injective as a map from \mathcal{S}_1 to \mathcal{S}_0 . The component ϕ_{01} naturally determines an element in the group $\text{Ext}_{\mathcal{R}_0}^1(\mathcal{S}, \mathcal{S})$. The above lemma can be interpreted as the vanishing of the subspace of this Ext group in $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ -grading $(-1, -1)$.

Lemma 4.3 follows from a slightly more general result, which we will periodically find useful:

Lemma 4.5. *Suppose that \mathcal{A} and \mathcal{B} are staircase complexes with absolute $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ -gradings and such that there is a grading preserving chain map $I: \mathcal{A} \rightarrow \mathcal{B}$ which is non-zero on homology. If $\phi: \mathcal{A} \rightarrow \mathcal{B}$ is a chain map of grading $(-1, -1)$, then ϕ is null-homotopic.*

Proof. The proof is essentially the same as [CZZ24, Lemma 5.19]. Write \mathcal{A} as $\text{Cone}(\partial_{\mathcal{A}}: \mathcal{A}_1 \rightarrow \mathcal{A}_0)$ and \mathcal{B} as $\text{Cone}(\partial_{\mathcal{B}}: \mathcal{B}_1 \rightarrow \mathcal{B}_0)$. The map ϕ can be written as $\phi = \phi_{01} + \phi_{10}$, where ϕ_{ij} maps \mathcal{A}_j to \mathcal{B}_i . Since $\partial_{\mathcal{A}}$ and $\partial_{\mathcal{B}}$ are injective, it is easy to see that ϕ_{10} is zero, so it suffices to show that $\phi = \phi_{01}$ is null-homotopic.

Let $\mathbf{x}_0, \mathbf{x}_2, \dots, \mathbf{x}_{2n}$ be the generators for \mathcal{A}_0 , and $\mathbf{x}_1, \mathbf{x}_3, \dots, \mathbf{x}_{2n-1}$ be the generators for \mathcal{A}_1 . Let i be the minimal index such that ϕ is non-zero on \mathbf{x}_i . The proof is by induction on i .

We consider two cases: $\phi(\mathbf{x}_i)$ is zero in homology, and $\phi(\mathbf{x}_i)$ is non-zero in homology. In the first case, if $\phi(\mathbf{x}_i) = \partial(\mathbf{y})$ for some $\mathbf{y} \in \mathcal{B}_1$, then we define a homotopy j which sends \mathbf{x}_i to \mathbf{y} . The map $\phi + \partial(j)$ vanishes on $\mathbf{x}_0, \dots, \mathbf{x}_i, \mathbf{x}_{i+1}$ (i.e. we have increased the minimal index on which ϕ is non-vanishing by 2). We now consider the case that $\phi(\mathbf{x}_i)$ is non-zero in homology. Write $\partial(\mathbf{x}_i) = \mathbf{x}_{i-1}W^n + \mathbf{x}_{i+1}Z^m$. Now $\text{gr}_{\mathbf{w}}(\mathbf{x}_{i+1}Z^m)$ has the same grading as $\phi(\mathbf{x}_i)$. We define a map $j: \mathcal{A} \rightarrow \mathcal{B}$ which sends \mathbf{x}_{i+1} to $I(\mathbf{x}_{i+1})Z^m$. Now $\phi + \partial(j)$ vanishes on $\mathbf{x}_0, \dots, \mathbf{x}_{i-1}$, and now sends \mathbf{x}_i to a boundary. Using the previous argument, we may modify ϕ by a chain homotopy so that it vanishes on $\mathbf{x}_0, \dots, \mathbf{x}_{i+1}$. By induction, the proof is complete. \square

Another helpful lemma is the following:

Lemma 4.6. *Suppose that \mathcal{S} is a staircase complex and $f: \mathcal{S} \rightarrow \mathcal{S}$ is a grading preserving chain homotopy equivalence. Then $f = \text{id}$.*

Proof. Write $\mathcal{S} = (\partial: \mathcal{S}_1 \rightarrow \mathcal{S}_0)$. Since f preserves the Maslov bigrading, it must also preserve the algebraic grading. Write $f_i = f|_{\mathcal{S}_i}$. Since $H_*(\mathcal{S})$ has rank 1 or 0 in each $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ -bigrading, the map f must induce the identity map on homology. We observe that for each generator \mathbf{x}_{2i} in algebraic grading 0, there are no other non-zero elements of \mathcal{S} in the same $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ -grading. Therefore $f(\mathbf{x}_{2i}) = \mathbf{x}_{2i}$. Since f is a chain map, we know that

$$\partial \circ f_1 = f_0 \circ \partial.$$

Since $f_0 = \text{id}$, we conclude that

$$\partial \circ (f_1 + \text{id}) = 0.$$

Since ∂ is injective as a map from \mathcal{S}_1 to \mathcal{S}_0 , we conclude $f_1 = \text{id}$. \square

An additional result that we will use concerns endomorphisms of staircases of positive degree:

Lemma 4.7. *Let \mathcal{S} be a staircase complex and $\phi: \mathcal{S} \rightarrow \mathcal{S}$ be a map which has $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ -grading (n, n) . If $n \geq 1$, then $\phi = 0$.*

Proof. Write $\mathbf{x}_0, \mathbf{x}_1, \dots, \mathbf{x}_{2n}$ for the generators of \mathcal{S} , ordered so that $\partial(\mathbf{x}_{2i+1}) = \mathbf{x}_{2i}W^{\alpha_i} + \mathbf{x}_{2i+2}Z^{\beta_i}$. We observe that

$$\text{gr}_{\mathbf{w}}(\mathbf{x}_{i+1}) < \text{gr}_{\mathbf{w}}(\mathbf{x}_i) \quad \text{and} \quad \text{gr}_{\mathbf{z}}(\mathbf{x}_{i+1}) > \text{gr}_{\mathbf{z}}(\mathbf{x}_i)$$

for all i . Suppose $\phi(\mathbf{x}_i)$ contains a summand of $\mathbf{x}_j W^a Z^b$. Suppose that $j \geq i$. Since ϕ has $\text{gr}_{\mathbf{w}}$ -grading n , we have $\text{gr}_{\mathbf{w}}(\mathbf{x}_j) - 2a = \text{gr}_{\mathbf{w}}(\mathbf{x}_i) + n$, or equivalently

$$\text{gr}_{\mathbf{w}}(\mathbf{x}_j) - \text{gr}_{\mathbf{w}}(\mathbf{x}_i) = n + 2a.$$

Since $j \geq i$, the left hand side is non-positive, while the right hand side is positive, so this is impossible. If $j \leq i$, the same argument applies with $\text{gr}_{\mathbf{z}}$ replacing $\text{gr}_{\mathbf{w}}$. This completes the proof. \square

5. THE CANDIDATE BIMODULE

In this section, we describe our candidate bimodule for a 2-component L-space link, equipped with framing $(0, 0)$. We will write ${}^{\mathcal{K}!}\mathcal{X}^{\text{alg}}(L)^{\mathcal{K}}$ for this bimodule. The candidate DA -bimodule, ${}_{\mathcal{K}}\mathcal{X}^{\text{alg}}(L)^{\mathcal{K}}$, is obtained by tensoring with the trace bimodule from Koszul duality (constructed in [Zem25]):

$${}_{\mathcal{K}}\mathcal{X}^{\text{alg}}(L)^{\mathcal{K}} := {}_{\mathcal{K}}[\mathcal{T}r]_{{\mathcal{K}}!} \boxtimes {}^{\mathcal{K}!}\mathcal{X}^{\text{alg}}(L)^{\mathcal{K}}.$$

5.1. The complexes at each idempotent.

5.1.1. *Idempotent $(0, 0)$.* We now describe the candidate module ${}^{\mathcal{K}!}\mathcal{X}^{\text{alg}}(L)^{\mathcal{K}}$ in idempotent $(0, 0)$. We will view this as a type- DD -module over $(\mathcal{R}_0^!, \mathcal{R}_0)$, and will write $\mathcal{R}_0^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_0}$.

Schematically, the bimodule $\mathcal{R}_0^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_0}$ takes the following form:

$$\begin{array}{ccccccc} \begin{array}{c} zw|L_{zw}+ \\ wz|L_{wz}+ \\ \theta|U \end{array} & & \begin{array}{c} zw|L_{zw}+ \\ wz|L_{wz}+ \\ \theta|U \end{array} & & \begin{array}{c} zw|L_{zw}+ \\ wz|L_{wz}+ \\ \theta|U \end{array} & & \begin{array}{c} zw|L_{zw}+ \\ wz|L_{wz}+ \\ \theta|U \end{array} & & \begin{array}{c} zw|L_{zw}+ \\ wz|L_{wz}+ \\ \theta|U \end{array} \\ \downarrow & \nearrow z|L_z & \downarrow & \nearrow z|L_z & \downarrow & \nearrow z|L_z & \downarrow & \nearrow z|L_z & \downarrow \\ \cdots \mathcal{C}_{s_1-2} & & \mathcal{C}_{s_1-1} & & \mathcal{C}_{s_1} & & \mathcal{C}_{s_1+1} & & \mathcal{C}_{s_1+2} \cdots \\ & \nwarrow w|L_w & \nwarrow w|L_w & \nwarrow w|L_w & \nwarrow w|L_w & \nwarrow w|L_w & \nwarrow w|L_w & & \end{array} \quad (5.1)$$

In the above, each of the complexes \mathcal{C}_{s_1} is a type- D module over \mathcal{R}_0 . We define each \mathcal{C}_{s_1} to be the canonical 2 step resolution of the module $\bigoplus_{s_2 \in \mathbb{Z} + \text{lk}(K_1, K_2)/2} \mathcal{HFL}(L, s_1, s_2)$. This is a torsion free complex by definition of an L-space link. As in Section 3.2, the free-resolution of this complex is a staircase complex.

In Equation (5.1), we choose the maps $L_w: \mathcal{C}_{s_1} \rightarrow \mathcal{C}_{s_1-1}$ and $L_z: \mathcal{C}_{s_1} \rightarrow \mathcal{C}_{s_1+1}$ to be any chain maps which have $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ -grading shift equal to $(-2, 0)$ and $(0, -2)$,

respectively, and which are non-zero on homology. Any two choices of maps for L_w are chain homotopic as type- D morphisms by Lemma 4.2, and similarly for L_z .

Before defining L_{zw} and L_{wz} , we set some notation. If $f: \mathcal{C}_{s_1} \rightarrow \mathcal{C}_{s'_1}$ is a type- D morphism, we write $\partial_{\text{int}}(f)$ for the morphism differential of f as a map of type- D modules.

We declare L_{zw} and L_{wz} to be any choice of maps such that

$$\partial_{\text{int}}(L_{zw}) = L_w \circ L_z + \text{id} \otimes U \quad \text{and} \quad \partial_{\text{int}}(L_{wz}) = L_z \circ L_w + \text{id} \otimes U,$$

which have $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ -grading equal to $(-1, -1)$, and which increase the algebraic grading (i.e. staircase grading) of \mathcal{C}_{s_1} by 1.

Remark 5.1. The above construction is essentially the same as the one appearing in [CZZ24, Section 5.5], with the maps L_w , L_z , L_{wz} and L_{zw} of our present work being the same as L_W , L_Z , $h_{Z,W}$ and $h_{W,Z}$ in [CZZ24]. The relation between the perspective in [CZZ24] and the above DD -bimodule is explained in [Zem25, Section 5.3].

A similar argument to [CZZ24, Proposition 5.9] shows that the induced bimodule $\mathcal{R}_0^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_0}$ is well-defined up to homotopy equivalence.

The groups $\bigoplus_{s_2 \in \mathbb{Z} + \text{lk}(K_1, K_2)/2} \mathcal{HFL}(L, s_1, s_2)$ can be read off from the H_L -function, as we now recall. Each of the groups $\mathcal{HFL}(L, s_1, s_2)$ is isomorphic to $\mathbb{F}[U]$ since L is an L-space link. By definition, the generator of $\mathcal{HFL}(L, s_1, s_2)$ has $\text{gr}_{\mathbf{w}}$ grading $-2H_L(s_1, s_2)$ and $\text{gr}_{\mathbf{z}}$ grading $-2H_L(s_1, s_2) - 2s_1 - 2s_2$. See, e.g., [CZZ25, Section 4.1].

5.1.2. Idempotent $(1, 0)$. We now describe the complexes appearing at idempotent $(1, 0)$. Let \mathcal{S} be the staircase complex $\mathcal{CFK}(K_2)$, viewed as a type- D module over $\mathbb{F}[W, Z]$. We define the complex $\mathcal{R}_1^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_0}$ to be the following:

$$\begin{array}{ccccccc} \dots & T^{s_1-2} \mathcal{S} & & T^{s_1-1} \mathcal{S} & & T^{s_1} \mathcal{S} & & T^{s_1+1} \mathcal{S} & & T^{s_1+2} \mathcal{S} \dots \\ & \uparrow & \swarrow & \uparrow & \swarrow & \uparrow & \swarrow & \uparrow & \swarrow & \uparrow \\ & \theta|U & \varphi_-|1 & \theta|U & \varphi_-|1 & \theta|U & \varphi_-|1 & \theta|U & \varphi_+|1 & \theta|U \end{array}$$

In the above, s_1 takes values in \mathbb{Z} .

We equip each $T^{s_1} \mathcal{S}$ with Maslov gradings $\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}}$ by identifying it with $\mathcal{CFK}(K_2)$. We define the A_2 Alexander grading $A_2 = \frac{1}{2}(\text{gr}_{\mathbf{w}} - \text{gr}_{\mathbf{z}})$. We view $T^{s_1} \mathcal{S}$ as being in A_1 Alexander grading s_1 .

5.1.3. Idempotent $(0, 1)$. We now consider idempotent $(0, 1)$. We define the complex $\mathcal{R}_0^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_1}$ abstractly as $\mathcal{R}_0^! \mathcal{X}(K_1)^{\mathbb{F}[U]} \otimes [1]^{\mathbb{F}[T, T^{-1}]}$, where $\mathcal{R}_0^! \mathcal{X}(K_1)^{\mathbb{F}[U]}$ is the idempotent 0 subspace of the surgery complex of the knot K_1 (treated as a DD -bimodule over $(\mathcal{R}_0^!, \mathbb{F}[U])$). In more detail, the AA -bimodule $\mathcal{K} \mathcal{X}(K_1)^{\mathbb{F}[U]}$ is described in [Zem21, Section 8]. The construction therein is naturally free on the right action of U (with the left \mathcal{K} -action being U -equivariant), and therefore this naturally describes a type- DA -bimodule $\mathcal{K} \mathcal{X}(K_1)^{\mathbb{F}[U]}$. We define the DD -bimodule $\mathcal{R}_0^! \mathcal{X}(K_1)^{\mathbb{F}[U]}$ by restricting the left idempotent, and tensoring with $\mathcal{R}_0^! [\mathcal{C}o]^{\mathcal{R}_0}$. The module $[1]^{\mathbb{F}[T, T^{-1}]}$ denotes a type- D structure with one generator, and vanishing differential.

Using the fact that K_1 is an L-space knot, we may produce the following model, which is smaller and the the one we focus on. Write $H_{K_1}: \mathbb{Z} \rightarrow \mathbb{Z}^{\geq 0}$ for the H -function

of K_1 . We will set

$$\eta(s_1) := H_{K_1}(s_1) - H_{K_1}(s_1 + 1),$$

which always takes value in $\{0, 1\}$. Then $\mathcal{R}_0^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_1}$ is given by the diagram

$$\begin{array}{ccccccc} \cdots \mathbf{y}_{-2} & \xrightarrow{z|U^{\eta(-2)}} & \mathbf{y}_{-1} & \xrightarrow{z|U^{\eta(-1)}} & \mathbf{y}_0 & \xrightarrow{z|U^{\eta(0)}} & \mathbf{y}_1 & \xrightarrow{z|U^{\eta(1)}} & \mathbf{y}_2 \cdots \\ \uparrow \scriptstyle \theta|U & \nwarrow \scriptstyle w|U^{1-\eta(-2)} & \uparrow \scriptstyle \theta|U & \nwarrow \scriptstyle w|U^{1-\eta(-1)} & \uparrow \scriptstyle \theta|U & \nwarrow \scriptstyle w|U^{1-\eta(0)} & \uparrow \scriptstyle \theta|U & \nwarrow \scriptstyle w|U^{1-\eta(1)} & \uparrow \scriptstyle \theta|U \end{array}$$

It is convenient to view $\mathcal{R}_0^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_1}$ as having the bigrading $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$, where

$$(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})(\mathbf{y}_{s_1}) = (-2H_{K_1}(s_1), -2H_{K_1}(s_1) - 2s_1).$$

We set

$$(A_1, A_2)(\mathbf{y}_{s_1}) = (s_1, 0).$$

5.1.4. *Idempotent (1, 1).* Finally, we describe the complexes $\mathcal{R}_1^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_1}$. We define this complex as the following diagram:

$$\begin{array}{ccccccc} \cdots T^{-2} \mathbf{e} & \xrightarrow{\varphi_+|1} & T^{-1} \mathbf{e} & \xrightarrow{\varphi_+|1} & T^0 \mathbf{e} & \xrightarrow{\varphi_+|1} & T^1 \mathbf{e} & \xrightarrow{\varphi_+|1} & T^2 \mathbf{e} \\ \uparrow \scriptstyle \theta|U & \nwarrow \scriptstyle \varphi_-|1 & \uparrow \scriptstyle \theta|U & \nwarrow \scriptstyle \varphi_-|1 & \uparrow \scriptstyle \theta|U & \nwarrow \scriptstyle \varphi_-|1 & \uparrow \scriptstyle \theta|U & \nwarrow \scriptstyle \varphi_+|1 & \uparrow \scriptstyle \theta|U \end{array}$$

We view the generator $T^{s_1} \mathbf{e}$ as having a single Maslov grading, gr , where $\text{gr}(T^{s_1} \mathbf{e}) = 0$. We view

$$(A_1, A_2)(T^{s_1} \mathbf{e}) = (s_1, 0).$$

5.2. **The length 1 maps.** We now define the length 1 maps of the surgery bimodule. In our bimodule $\mathcal{K}^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{K}}$, these are the components which shift only one idempotent. (The term *length* comes from the perspective of the link surgery complex from [MO10] as a hypercube, where the “length” refers to the L^1 -length of the corresponding line segment in the cube).

5.2.1. *Idempotent (0, 0) to (1, 0).* The maps from idempotent (0, 0) to idempotent (1, 0) are described (in slightly different language) in [CZZ24, Section 5.4]. We repeat the description in our present notation. We pick maps

$$L_s, L_t: \mathcal{C}_{s_1} \rightarrow T^{s_1 - \ell/2} \otimes \mathcal{S}$$

which are chain maps and are non-zero on homology, preserve the staircase grading, and which have the following Maslov gradings:

$$(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})(L_s) = (0, -2s_1 + \ell) \quad \text{and} \quad (\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})(L_t) = (2s_1 + \ell, 0).$$

Additionally, we pick maps

$$L_{zs}: \mathcal{C}_{s_1} \rightarrow T^{s_1 - \ell/2 + 1} \mathcal{S} \quad \text{and} \quad L_{wt}: \mathcal{C}_{s_1} \rightarrow T^{s_1 - \ell/2 - 1} \mathcal{S}.$$

We assume that these maps increase the algebraic (staircase) grading by 1, and have grading

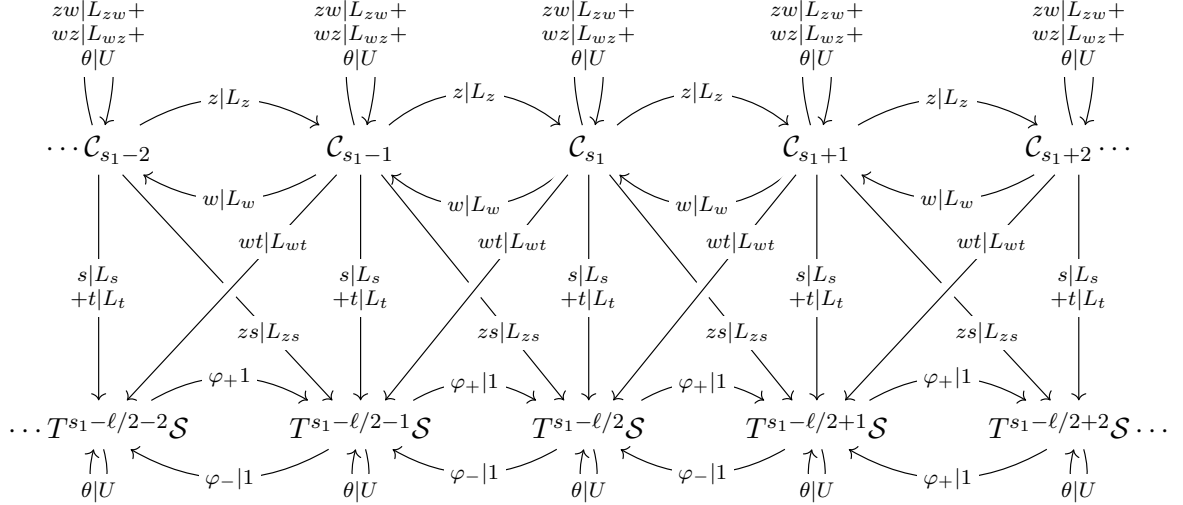

$$(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})(L_{zs}) = (1, -2s_1 + \ell - 1) \quad \text{and} \quad (\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})(L_{wt}) = (2s_1 + \ell - 1, 1).$$

Additionally, we require these maps to satisfy

$$\partial_{\text{int}}(L_{zs}) = L_s \circ L_z + L_{\varphi_+} \circ L_\sigma \quad \text{and} \quad \partial_{\text{int}}(h_{wt}) = L_t \circ L_w + L_{\varphi_-} \circ L_t.$$

In the above, $L_{\varphi_\pm}: T^{s_1 \pm 1} \mathcal{S} \rightarrow T^{s_1 \pm 1} \otimes \mathcal{S}$ are the canonical identifications.

We form the components of $\delta^{1,1}$ from idempotent $(0,0)$ to $(1,0)$ by using the above maps. The maps L_s are weighted by s . The maps L_t are weighted by t . The maps L_{zs} are weighted by zs . The maps L_{wt} are weighted by wt . We arrange these as shown below:

It is convenient to write Ψ^{K_1} for the components of the above diagram which are weighted by multiples of s , and to write Ψ^{-K_1} for the components of the above diagram which are weighted by multiples of t .

Remark 5.2. In [CZZ24, Section 5.5], we wrote L_σ , L_τ , $h_{\sigma,Z}$ and $h_{\tau,W}$ for the maps we write L_s , L_t , L_{zs} , and L_{wt} above (respectively). In [CZZ24, Section 5.5], we also included choices of homotopies $h_{\sigma,W}$ and $h_{\tau,Z}$, though it is explained in [Zem25, Remark 5.3] that these contain redundant information and do not appear in the Koszul dual type- DD bimodule.

5.2.2. Idempotent $(0,0)$ to $(0,1)$. We now describe the components of the differential on ${}^{\mathcal{K}^!}\mathcal{X}^{\text{alg}}(L)^{\mathcal{K}}$ which go from idempotent $(0,0)$ to $(0,1)$. Write $(\sigma), (\tau) \subseteq \mathcal{K}$ for the ideals generated by σ and τ , respectively. We pick

$$R^\sigma: \mathcal{C}_{s_1} \rightarrow \mathbf{y}_{s_1-\ell/2} \otimes (\sigma) \quad \text{and} \quad R^\tau: \mathcal{C}_{s_1} \rightarrow \mathbf{y}_{s_1+\ell/2} \otimes (\tau)$$

to be the unique maps satisfying the following properties

- (1) R^σ and R^τ are chain maps.
- (2) R^σ and R^τ vanish on algebraic grading 1, and are non-vanishing on each monomial generator of \mathcal{C}_s in algebraic grading 0.
- (3) The maps R^σ and R^τ are homogeneously graded with respect to the Alexander grading and to furthermore satisfy

$$A_1(R^\sigma) = -\ell/2, \quad A_1(R^\tau) = \ell/2,$$

and

$$A_2(R^\tau) = A_2(R^\sigma) = -\ell/2.$$

(See Equation (3.2) our grading conventions).

- (4) On each Alexander grading in $\mathbb{H}(L)$, R^σ and R^τ are homogeneously graded with respect to $(\text{gr}_w, \text{gr}_z)$. On generators which lie in Alexander grading (s_1, s_2) , they have grading $(\text{gr}_w, \text{gr}_z)(R^\sigma) = (0, 2s_2 + \ell)$ and $(\text{gr}_w, \text{gr}_z)(R^\tau) = (-2s_2 + \ell, 0)$.

When defining the grading of the maps R^σ and R^τ , we are viewing an element $\mathbf{y}_s \otimes U^i T^j \sigma$ as having

$$(\text{gr}_w, \text{gr}_z)(\mathbf{y}_{s_1} \otimes U^i T^j \sigma) = (\text{gr}_w, \text{gr}_z)(\mathbf{y}_{s_1}) - (2i, 2j),$$

and

$$(A_1, A_2)(\mathbf{y}_{s_1} \otimes U^i T^j \sigma) = (s_1, j),$$

and similarly for τ -weighted elements.

We use the map $1|R^\sigma + 1|R^\tau$ as the component of the differential from $\mathcal{R}_0^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_0}$ to $\mathcal{R}_0^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_1}$.

Schematically, we indicate this below:

The following is straightforward, and we leave the proof to the reader:

Lemma 5.3. *The maps R^σ and R^τ are chain maps of type-DD modules from $\mathcal{R}_0 \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_0}$ to $\mathcal{R}_0 \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_1}$.*

Note that in the above, when we say that R^σ is a chain map from $\mathcal{R}_0 \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_0}$ to $\mathcal{R}_0 \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_1}$, we are viewing both \mathcal{R}_0 and \mathcal{R}_1 as being inside of \mathcal{K} , and therefore viewing both modules as *DD* bimodules over $(\mathcal{R}_0, \mathcal{K})$. Furthermore, when we call these maps chain maps, we mean that the morphism differential vanishes on them.

5.2.3. Idempotent $(1, 0)$ to $(1, 1)$. The staircase complex $\mathcal{S} = \mathcal{CFK}(K_2)$ extends to a type-D structure $\mathcal{X}_0(K_2)^{\mathcal{K}}$, which is normalized so that $\mathcal{X}_0(K_2) \cdot \mathbf{I}_1$ consists of a single generator, concentrated in (gr, A) grading 0. See [HMSZ25, Section 5.3] for more details. Let δ^σ and δ^τ denote the components of the structure map on $\mathcal{X}_0(K_2)^{\mathcal{K}}$ which are weighted by σ and τ .

We define maps Ψ^{K_2} and Ψ^{-K_2} from $\mathcal{R}_1^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_0}$ to $\mathcal{R}_1^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_1}$ via the formulas

$$\Psi^{K_2} = 1 \otimes L_{T^0} \otimes \delta^\sigma \quad \text{and} \quad \Psi^{-K_2} = 1 \otimes L_{T^\ell} \otimes \delta^\tau.$$

Here L_{T^i} is the endomorphism of $\mathbb{F}[T, T^{-1}]$ which is multiplication by T^i . We define the components of the differential $\delta^{1,1}$ of $\kappa^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{K}}$ which go from $\mathcal{R}_1^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_0}$ to $\mathcal{R}_1^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_1}$ to be the sum of Ψ^{K_2} and Ψ^{-K_2} .

5.2.4. *Idempotent (0, 1) to (1, 1).* Finally, we define the component of $\delta^{1,1}$ which goes from $\mathcal{R}_0^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_1}$ to $\mathcal{R}_1^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_1}$. We recall that the underlying vector spaces of $\mathcal{R}_0^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_1}$ and $\mathcal{R}_1^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_1}$ are identified with the idempotent 0 and 1 subspaces of the type- D -structure

$$\kappa^! \mathcal{X}_0(K_1)^{\mathbb{F}[U]} = \kappa^! [\text{Co}]^{\mathcal{K}} \boxtimes_{\mathcal{K}} \mathcal{X}_0(K_1)^{\mathbb{F}[U]}$$

(which as vector spaces are the same as the idempotent 0 and 1 subspaces of $\kappa \mathcal{X}_0(K_1)^{\mathbb{F}[U]}$). Write $L_\sigma, L_\tau: \mathbf{I}_0 \cdot \mathcal{X}_0(K_1) \rightarrow \mathbf{I}_1 \cdot \mathcal{X}_0(K_1)$ for the structure maps $\delta_2^1(\sigma, -)$ and $\delta_2^1(\tau, -)$. Then the differentials from $\mathcal{R}_0^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_1}$ to $\mathcal{R}_1^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_1}$ are given by $s \otimes L_\sigma$ and $t \otimes T^\ell L_\tau$, as shown in the diagram below:

Remark 5.4. In the above diagram, the T^ℓ weight on the arrows $t|T^\ell L_\tau$ is part of the \mathcal{R}_1 output of the map. This is not the same as the T -powers shown along the bottom row, which are part of the vector space of the module $\mathcal{R}_1^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_1}$.

5.3. **The length 2 maps.** We define the complex $\kappa^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{K}}$ to have vanishing length 2 map. (By length 2 map, we mean the component of $\delta^{1,1}$ which goes from idempotent (0, 0) to (1, 1)).

Having defined the structure map $\delta^{1,1}$ on $\kappa^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{K}}$, we state the following:

Proposition 5.5. *The bimodule $\kappa^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{K}}$ satisfies the type-DD structure relation, and furthermore is well-defined up to U -equivariant homotopy equivalence.*

We leave the proof to the reader. Compare [CZZ24, Proposition 5.10].

6. PROOF OF THE EQUIVALENCE

In this section, we prove the following theorem:

Proposition 6.1. *If L is a 2-component L -space link in S^3 , and \mathcal{A} is an arc-system such that $\kappa^! \mathcal{X}(L, \mathcal{A})^{\mathcal{K}}$ admits a U -equivariant model, then there is a homotopy equivalence*

$$\kappa^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{K}} \simeq \kappa^! \mathcal{X}(L, \mathcal{A})^{\mathcal{K}}.$$

Recall that $\mathcal{K}^!$ is obtained by completing $\mathcal{K}^!$ by the weight filtration on idempotent $(0, 0)$. That is, we allow infinite sums of monomials in idempotent $(0, 0)$ with increasing weight, such as $\sum_{i=0}^{\infty} (wz)^i$. In the subsequent Section 7, we prove that the homotopy equivalence holds also over the uncompleted algebra $\mathcal{K}^!$.

Remark 6.2. In our proof of Proposition 6.1, we the U -equivariant assumption is only necessary to determine the length 2 map of the complex (i.e. the component of $\delta^{1,1}$ which shifts both idempotents). We note that our computation of ${}_{\mathcal{K}}\mathcal{X}(L)^{\mathcal{R}_0}$ in [CZZ24] never used the U -equivariance property. In our present paper, we assume the U -equivariance condition even where it is not necessary, because it simplifies our proofs. Nonetheless, the techniques of this paper extend easily to handle the cases where the U -equivariance condition is unnecessary, such as for the bimodule ${}_{\mathcal{K}}\mathcal{X}(L)^{\mathcal{R}_0}$. We leave these details as an exercise to the interested reader.

6.1. L-space knots and staircases. In this section, we recall [CZZ24, Theorem 5.14]:

Lemma 6.3. *Suppose that $\mathcal{C}^{\mathcal{R}_0}$ is a type- D structure admitting a $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ -bigrading whose homology module $\mathcal{H}_{\mathcal{R}_0}$ (i.e. the homology of $\mathcal{C}^{\mathcal{R}_0} \boxtimes \mathcal{R}_0$ equipped with only m_2 non-vanishing) has support contained in $2\mathbb{Z} \times 2\mathbb{Z}$. Then $\mathcal{C}^{\mathcal{R}_0}$ is homotopy equivalent to a free resolution of $\mathcal{H}_{\mathcal{R}_0}$.*

Proof. By definition, $\mathcal{H}_{\mathcal{R}_0}$ is quasi-isomorphic to a free resolution of itself. If A is an algebra over a field, then in the category of A_{∞} -modules over A , quasi-isomorphisms admit inverses as A_{∞} module maps (see [Kel01, Theorem, pg 14]), so $\mathcal{H}_{\mathcal{R}_0}$ is homotopy equivalent to a free resolution of itself as an A_{∞} -module.

By homological perturbation theory, we can equip the underlying vector space of $\mathcal{H}_{\mathcal{R}_0}$ with an A_{∞} -module structure, denoted $\tilde{\mathcal{H}}_{\mathcal{R}_0}$, so that

$$\tilde{\mathcal{H}}_{\mathcal{R}_0} \simeq \mathcal{C}^{\mathcal{R}_0} \boxtimes {}_{\mathcal{R}_0}[\mathcal{R}_0]_{\mathcal{R}_0}.$$

The bimodule ${}_{\mathcal{R}_0}[\mathcal{R}_0]_{\mathcal{R}_0}$ is quasi-invertible, with quasi-inverse equal to the rank four type- DD bimodule ${}^{\mathcal{R}_0}\Lambda^{\mathcal{R}_0}$ shown below:

$$\begin{array}{ccc} & 1 & \xrightarrow{W \otimes 1 + 1 \otimes W} \phi \\ {}_{\mathcal{R}_0}\Lambda^{\mathcal{R}_0} := Z \otimes 1 + 1 \otimes Z & \downarrow & \downarrow Z \otimes 1 + 1 \otimes Z \\ & \psi & \xrightarrow{W \otimes 1 + 1 \otimes W} \phi \psi. \end{array}$$

The above is well known, and essentially the Koszul resolution of a module over \mathcal{R}_0 , but we refer the reader to [CZZ24, Lemma 5.11] for a proof in our present notation. We observe that the action $m_3(-, a, b)$ from $\tilde{\mathcal{H}}_{\mathcal{R}_0}$ shifts both of the $\text{gr}_{\mathbf{w}}$ and $\text{gr}_{\mathbf{z}}$ grading by 1, modulo 2, for any $a, b \in \mathcal{R}_0$. This implies that $m_3(-, a, b)$ vanishes on $\tilde{\mathcal{H}}_{\mathcal{R}_0}$ because \mathcal{H} is supported only in even $\text{gr}_{\mathbf{w}}$ and $\text{gr}_{\mathbf{z}}$ gradings. In particular,

$$\tilde{\mathcal{H}}_{\mathcal{R}_0} \boxtimes {}^{\mathcal{R}_0}\Lambda^{\mathcal{R}_0} \simeq \mathcal{H}_{\mathcal{R}_0} \boxtimes {}^{\mathcal{R}_0}\Lambda^{\mathcal{R}_0},$$

from which we conclude that $\mathcal{H}_{\mathcal{R}_0} \simeq \tilde{\mathcal{H}}_{\mathcal{R}_0}$. \square

Remark 6.4. The above lemma gives another proof (or at least another perspective on the proof) of Ozsváth and Szabó's result [OS05] that the knot Floer complexes of L-space knots are homotopy equivalent to staircase complexes. Indeed, if K is an L-space

knot, its homology $\mathcal{HFK}(K)$ can naturally be viewed as a monomial ideal in $\mathbb{F}[W, Z]$, and is supported in even $\text{gr}_{\mathbf{w}}$ and $\text{gr}_{\mathbf{z}}$ grading. The above lemma implies that $\mathcal{CFK}(K)$ is a free resolution of $\mathcal{HFK}(K)$, which is a staircase complex.

6.2. The complexes at each idempotent. In this section, we will prove the following:

Proposition 6.5. *Suppose that $L \subseteq S^3$ is a 2-component L-space link and that ${}^{\mathcal{K}!}\mathcal{X}(L)^{\mathcal{K}}$ is a U -equivariant model of the link surgery complex of L . Write $\mathcal{R}_{\varepsilon}\mathcal{X}(L)^{\mathcal{R}_{\varepsilon'}}$ for the complex at idempotent $(\varepsilon, \varepsilon')$. Then there is a U -equivariant homotopy equivalence*

$$\mathcal{R}_{\varepsilon}\mathcal{X}(L)^{\mathcal{R}_{\varepsilon'}} \simeq \mathcal{R}_{\varepsilon}\mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_{\varepsilon'}}.$$

When $\varepsilon = 0$, the equivalence is over the completed ring $\mathcal{R}_0^!$.

Proposition 6.1 follows from Lemmas 6.7, 6.8 and 6.9, below.

6.2.1. Idempotent $(0, 0)$. For each $s_1 \in \mathbb{Z} + \text{lk}(K_1, K_2)/2$, we write X_{s_1} and \mathcal{C}_{s_1} for subspaces of $\mathcal{R}_0^!\mathcal{X}(L)^{\mathcal{R}_0}$ and $\mathcal{R}_0^!\mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_0}$ which have A_1 -Alexander grading s_1 . We view X_{s_1} and \mathcal{C}_{s_1} as type- D structures over \mathcal{R}_0 by equipping them with the component of $\delta^{1,1}$ which is weighted by $1 \in \mathcal{R}_0^!$.

Lemma 6.6. *For all s_1 , there is a strong deformation retraction*

$$H \hookrightarrow X_{s_1} \xrightleftharpoons[I]{\Pi} \mathcal{C}_{s_1}.$$

We recall that a strong deformation retraction is a diagram as above so that

$$\Pi \circ I = \mathbb{I}_{\mathcal{C}_{s_1}}, \quad I \circ \Pi = \mathbb{I}_{X_{s_1}} + \partial(H), \quad H \circ H = 0, \quad H \circ I = 0, \quad \Pi \circ H = 0.$$

Proof. The homology of X_{s_1} and \mathcal{C}_{s_1} are both isomorphic to

$$\bigoplus_{s_2 \in \mathbb{Z} + \text{lk}(K_1, K_2)/2} \mathcal{HFL}(L, s_1, s_2). \quad (6.1)$$

Since L is an L-space link, the group appearing in Equation (6.1) is supported only in even $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ gradings. By Lemma 6.3, X_{s_1} must be homotopy equivalent to a staircase complex. We have, therefore, a diagram

$$Q \hookrightarrow X_{s_1} \xrightleftharpoons[I]{\Pi} \mathcal{C}_{s_1} \hookrightarrow J$$

where $\Pi \circ I = \mathbb{I}_{X_s} + \partial(J)$ and $I \circ \Pi = \mathbb{I}_{\mathcal{C}_s} + \partial(Q)$. As a first step, we observe that since \mathcal{C}_{s_1} is reduced (i.e. the differential has image in the maximal ideal (W, Z)), the homotopy equivalence $\Pi \circ I: \mathcal{C}_{s_1} \rightarrow \mathcal{C}_{s_1}$ must be invertible as a type- D module map (alternatively, we could use Lemma 4.6 which is particular to staircases). By composing Π with the inverse of this map, we may assume that $\Pi \circ I = \mathbb{I}_{\mathcal{C}_{s_1}}$.

The following formula of Lambe and Stasheff [LS87, Section 2.1] gives a homotopy $H: X_{s_1} \rightarrow X_{s_1}$ which turns the above diagram into a strong deformation retraction:

$$\begin{aligned} Q' &= (\mathbb{I} + I \circ \Pi) \circ Q \circ (\mathbb{I} + I \circ \Pi) \\ H &= Q' \circ \partial_{X_{s_1}} \circ Q', \end{aligned}$$

completing the proof. \square

Lemma 6.7. *If L is a 2-component L -space link and $\mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_0}$ is U -equivariant, then there is a U -equivariant homotopy equivalence of DD -bimodules $\mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_0} \rightarrow \mathcal{R}_0^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_0}$.*

Proof. We will write the structure map $\mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_0}$ as

$$\delta^{1,1} = d^{1,1} + \alpha^{1,1},$$

where $d^{1,1}$ consists only of the differentials weighted by $1 \in \mathcal{R}_0^!$, and $\alpha^{1,1}$ consists of the components weighted by monomials of $\mathcal{R}_0^!$ with weight 1 or greater.

We will write $\delta_{\text{alg}}^{1,1}$ also as $d_{\text{alg}}^{1,1} + \alpha_{\text{alg}}^{1,1}$ where $d_{\text{alg}}^{1,1}$ and $\alpha_{\text{alg}}^{1,1}$ are defined similarly to the above. Lemma 6.6 gives a strong deformation retraction of type- D modules over \mathcal{R}_0

$$H \begin{array}{c} \curvearrowright \\ \curvearrowleft \end{array} \left(\bigoplus_{s_1} X_{s_1}, d^{1,1} \right) \begin{array}{c} \xrightarrow{\Pi} \\ \xleftarrow{I} \end{array} \left(\bigoplus_{s_1} \mathcal{C}_{s_1}, d_{\text{alg}}^{1,1} \right).$$

The endomorphism $(1 + H \circ \alpha^{1,1})$ is invertible when we work over $\mathcal{R}_0^!$, since the inverse is given by

$$\sum_{i=0}^{\infty} (H \circ \alpha^{1,1})^i.$$

The homological perturbation lemma for type- DD modules (compare [LS87, Section 2], which states the perturbation lemma for chain complexes) gives a homotopy equivalence (in fact, a strong deformation retraction)

$$\left(\bigoplus_{s_1} X_{s_1}, d^{1,1} \right) \simeq \left(\bigoplus_{s_1} \mathcal{C}_{s_1}, d_{\text{alg}}^{1,1} + \beta^{1,1} \right)$$

where

$$\beta^{1,1} = \sum_{n \geq 0} \Pi \circ \alpha^{1,1} \circ (H \circ \alpha^{1,1})^n \circ I.$$

Since $H \circ H = 0$, it is easy to see that $\beta^{1,1}$ is U -equivariant (i.e. the only self arrows consist of $\theta \otimes \text{id} \otimes U$), as are the maps appearing in the above homotopy equivalence.

By replacing $\mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_0}$ with $(\bigoplus_{s_1} \mathcal{C}_{s_1}, d_{\text{alg}}^{1,1} + \beta^{1,1})$, we can regard $\mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_0}$ and $\mathcal{R}_0^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_0}$ as having the same underlying vector space, and also the same induced type- D structures over \mathcal{R}_0 . We will write $\mathcal{X}(L)$ and \mathcal{C}_{s_1} for the common underlying vector spaces and type- D structures over \mathcal{R}_0 . We will write $\delta^{1,1}$ for the structure maps from $\mathcal{X}(L)$, and we will write $\delta_{\text{alg}}^{1,1}$ for the structure maps from $\mathcal{X}^{\text{alg}}(L)$.

Next, we observe that the w and z weighted terms of $\delta^{1,1}$ have the same $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ -gradings as the maps L_w and L_z , defined in Section 5.1. Furthermore, they cannot be null-homotopic as chain maps from \mathcal{C}_{s_1} to $\mathcal{C}_{s_1 \pm 1}$ because by Koszul duality the w weighted component of $\delta^{1,1}$ corresponds to the action of W_1 on $\mathcal{HFL}(L)$, which acts non-trivially on homology because $W_1 Z_1 = U_1$, and $\mathcal{HFL}(L)$ is a free and non-zero $\mathbb{F}[U_1]$ -module by definition. A similar statement holds for the z -weighted component. Also, since the w and z weighted components preserve the $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ -gradings modulo 2, it is easy to see that they must preserve the algebraic (staircase) grading on \mathcal{C}_{s_1} .

Therefore in the construction of $\mathcal{R}_0^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_0}$, we can take L_w and L_z to be w and z components of $\delta^{1,1}$ from $\mathcal{X}(L)$.

Next, we consider the components of $\delta^{1,1}$ which are weighted by wz or zw . Call these L_{wz} and L_{zw} , respectively. *A-priori*, L_{wz} and L_{zw} may have summands which increase the algebraic grading by 1, or decrease it by 1. Write L_{wz}^{10}, L_{zw}^{10} and L_{wz}^{01}, L_{zw}^{01} for each of these summands, respectively. We now modify $(\mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_0}, \delta^{1,1})$ by a homotopy equivalence so that L_{wz} and L_{zw} increase the algebraic grading, i.e. so that L_{wz}^{01} vanishes. By Lemma 4.3, the maps L_{wz}^{01} and L_{zw}^{01} are null-homotopic. Write $h_{wz}, h_{zw}: \mathcal{C}_{s_1} \rightarrow \mathcal{C}_{s_1} \otimes \mathcal{R}_0$ for the null-homotopies. We define an endomorphism $h = wz \otimes h_{wz} + zw \otimes h_{zw}$ of $(\mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_0}, \delta^{1,1})$. Note that $1+h$ is invertible over the completed ring $\mathcal{R}_0^!$, so if we apply Lemma 2.1, we see that $(\mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_0}, \delta^{1,1})$ is isomorphic to a DD -bimodule whose underlying vector space is $\mathcal{X}(L)$, and whose w, z, wz and zw weighted differentials coincide with those of $\delta_{\text{alg}}^{1,1}$ (but which may have differentials weighted by algebra elements in $\mathcal{R}_0^!$ with weight larger than 2). Abusing notation slightly, write $\delta^{1,1}$ for the new structure map on $\mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_0}$ after this perturbation.

We now eliminate the higher weight differentials of $\delta^{1,1}$, by an inductive procedure which repeats the ideas used to modify the weight 1 and 2 differentials of $\delta^{1,1}$. Write L_{wzw} and $L_{z wz}$ for the summands of $\delta^{1,1}$ which are weighted by wzw and $z wz$, respectively. We observe that $L_{z wz}$ and L_{wzw} have the same $(\text{gr}_w, \text{gr}_z)$ -gradings as L_w and L_z . By considering the wzw coefficient of the type- DD -structure relation for $\delta^{1,1}$, we see that

$$\partial_{\text{int}}(L_{wzw}) + L_w \circ L_{wz} + L_{zw} \circ L_z = 0.$$

Since $\delta_{\text{alg}}^{1,1}$ satisfies the type- DD structure relation, and $\delta_{\text{alg}}^{1,1}$ has no components with $\mathcal{R}_0^!$ -weight larger than 2, and since $\delta_{\text{alg}}^{1,1}$ coincides with $\delta^{1,1}$ on components with $\mathcal{R}_0^!$ weight 2 or less, we conclude that $L_w \circ L_{wz} + L_{zw} \circ L_z = 0$. In particular, L_{wzw} is a chain map when viewed as a type- D morphism from \mathcal{C}_{s_1} to \mathcal{C}_{s_1-1} . The same logic shows that $L_{z wz}$ is also a chain map from \mathcal{C}_{s_1} to \mathcal{C}_{s_1+1} .

When we examine the $wzwz$ coefficient of the type- DD structure relation for $\delta^{1,1}$, we see that

$$0 \simeq L_z \circ L_{wzw} + L_{z wz} \circ L_w + L_{wz} \circ L_{wz} = L_z \circ L_{wzw} + L_{z wz} \circ L_w, \quad (6.2)$$

as type- D endomorphisms of \mathcal{C}_{s_1} . (The homotopy is given by L_{wzwz} and we are also using the fact that $L_{wz} \circ L_{wz} = 0$ because L_{wz} increases the algebraic grading by 1). Recall that the maps L_w and L_z are, up to chain homotopy, the unique chain maps from \mathcal{C}_{s_1} to $\mathcal{C}_{s_1 \pm 1}$ in their grading which are non-zero on homology. Equation (6.2) implies that, for each s_1 , the maps

$$L_{z wz}: \mathcal{C}_{s_1-1} \rightarrow \mathcal{C}_{s_1} \quad \text{and} \quad L_{wzw}: \mathcal{C}_{s_1} \rightarrow \mathcal{C}_{s_1-1}$$

are either both non-zero on homology, or both zero on homology (though the property of being zero or non-zero may depend on s_1). Define a function

$$\epsilon: \mathbb{Z} + \text{lk}(K_1, K_2)/2 \rightarrow \mathbb{Z}/2$$

as follows. We set $\epsilon(s_1) = 1$ if and only $L_{z wz}: \mathcal{C}_{s_1-1} \rightarrow \mathcal{C}_{s_1}$ and $L_{wzw}: \mathcal{C}_{s_1} \rightarrow \mathcal{C}_{s_1-1}$ are non-zero on homology. Then we define a map

$$h: \mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_0} \rightarrow \mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_0}$$

which sends $\mathbf{x} \in \mathcal{C}_{s_1}$ to $\epsilon(s_1)wz \otimes \mathbf{x}$. Observe that $1+h$ is invertible over the completed algebra \mathcal{R}_0^\dagger , so we can apply Lemma 2.1 using the function h described above, to modify $(\mathcal{R}_0^\dagger \mathcal{X}(L), \delta^{1,1})$ to an isomorphic type- DD structure whose wzw terms change to $L_{wzw} + \epsilon(s_1)L_w$ and whose zwz terms change to $L_{zwz} + \epsilon(s_1+1)L_z$. The components weighted by \mathcal{R}_0^\dagger -elements of weight less than 3 are unchanged. After this modification, all of the maps h_{zwz} and h_{wzw} are still chain maps (when viewed as maps from \mathcal{C}_{s_1} to $\mathcal{C}_{s_1 \pm 1}$), however they are all null-homotopic. Abusing notation, we write $(\mathcal{R}_0^\dagger \mathcal{X}(L)^{\mathcal{R}_0}, \delta^{1,1})$ for the complex with this modified structure map.

We let $j_{zwz} : \mathcal{C}_{s_1} \rightarrow \mathcal{C}_{s_1+1}$ and $j_{wzw} : \mathcal{C}_{s_1} \rightarrow \mathcal{C}_{s_1-1}$ be suitably graded null-homotopies. We define a map

$$h' : \mathcal{R}_0^\dagger \mathcal{X}(L)^{\mathcal{R}_0} \rightarrow \mathcal{R}_0^\dagger \mathcal{X}(L)^{\mathcal{R}_0}$$

by sending $\mathbf{x} \in \mathcal{C}_{s_1}$ to $wzw \otimes j_{zwz}(\mathbf{x}) + zwz \otimes j_{wzw}(\mathbf{x})$. After modifying $(\mathcal{R}_0^\dagger \mathcal{X}(L)^{\mathcal{R}_0}, \delta^{1,1})$ using Lemma 2.1 with the function h' , we have produced a homotopy equivalent model whose differential coincides with our candidate model $\delta_{\text{alg}}^{1,1}$ on monomials of \mathcal{R}_0^\dagger up to \mathcal{R}_0^\dagger -weight 3. Furthermore, this model and the homotopy equivalence are easily seen to be U -equivariant. We again will write $(\mathcal{R}_0^\dagger \mathcal{X}(L)^{\mathcal{R}_0}, \delta^{1,1})$ for the new complex.

A similar argument works to eliminate components of $\delta^{1,1}$ which are weighted by $wzwz$ or $zwzw$. Write

$$L_{wzwz}, L_{zwzw} : \mathcal{C}_{s_1} \rightarrow \mathcal{C}_{s_1}$$

for the components of $\delta^{1,1}$ which are weighted by $wzwz$ and $zwzw$, respectively. Similar to before, it is straightforward to see that L_{wzwz} and L_{zwzw} are chain maps. Furthermore, we observe that they both have $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ degree $(-1, -1)$. Write $\mathcal{C}_{s_1} = (\partial_{s_1} : \mathcal{C}_{s_1}^1 \rightarrow \mathcal{C}_{s_1}^0)$. The map L_{wzwz} decomposes as a sum $L_{wzwz}^{10} + L_{wzwz}^{01}$, where L_{wzwz}^{ij} maps algebraic grading j to algebraic grading i . Since ∂_{s_1} is injective, we see that L_{wzwz}^{10} must vanish. The map L_{wzwz}^{01} is null-homotopic by Lemma 4.3. By a similar argument, L_{zwzw} is also null-homotopic. Therefore, we may remove the differentials weighted by $wzwz$ and $zwzw$ by applying Lemma 2.1.

Proceeding inductively, if we construct a model for $(\mathcal{R}_0^\dagger \mathcal{X}(L)^{\mathcal{R}_0}, \delta^{1,1})$ so that $\delta^{1,1}$ and $\delta_{\text{alg}}^{1,1}$ agree up to \mathcal{R}_0^\dagger -weight n , for some $n \geq 4$, we now modify $(\mathcal{R}_0^\dagger \mathcal{X}(L)^{\mathcal{R}_0}, \delta^{1,1})$ using Lemma 2.1 so that $\delta^{1,1}$ agrees with $\delta_{\text{alg}}^{1,1}$ up to monomials of \mathcal{R}_0^\dagger -weight $n+1$. If $n+1$ is even, we may use the same argument as for removing the $wzwz$ and $zwzw$ weighted terms. If $n+1$ is odd, we may use the same argument as for removing the wzw and zwz weighted terms.

This produces an infinite sequence of maps

$$f_n : \mathcal{X}(L) \rightarrow \mathcal{R}_0^\dagger \otimes \mathcal{X}(L) \otimes \mathcal{R}_0$$

which are isomorphisms of DD -modules (for suitable structure maps $\delta^{1,1}$). The maps f_n are all equal to $\text{id} + f'_n$, where f'_n involves only monomials of \mathcal{R}_0^\dagger of length at least n . Therefore the infinite composition $\cdots \circ f_3 \circ f_2 \circ f_1$ is well-defined, and gives homotopy equivalence between our original type- D structure $\mathcal{R}_0^\dagger \mathcal{X}(L)^{\mathcal{R}_0}$ and $\mathcal{R}_0^\dagger \mathcal{X}_{\text{alg}}(L)^{\mathcal{R}_0}$. As described earlier, all of these maps are U -equivariant, and it is easy to see that their inverses are as. \square

6.2.2. *Idempotent* $(1, 0)$. We now consider idempotent $(1, 0)$, i.e. $\mathbf{I}_1 \cdot \mathcal{X}(L) \cdot \mathbf{I}_0$.

Lemma 6.8. *Suppose that $\mathcal{R}_1^! \mathcal{X}(L)^{\mathcal{R}_0}$ has U -equivariant structure maps. Then there is a U -equivariant homotopy equivalence $\mathcal{R}_1^! \mathcal{X}(L)^{\mathcal{R}_0} \simeq \mathcal{R}_1^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_0}$.*

Proof. The proof is similar to the proof of Lemma 6.7. Write X_{s_1} and $T^{s_1} \otimes \mathcal{S}$ for the subspaces of $\mathcal{R}_1^! \mathcal{X}(L)^{\mathcal{R}_0}$ and $\mathcal{R}_1^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_0}$ whose A_1 -Alexander grading is s_1 . By using only the components of the structure map $\delta^{1,1}$ which are weighted by $1 \in \mathcal{R}_1^!$, we may view X_{s_1} and $T^{s_1} \otimes \mathcal{S}$ as type- D modules over \mathcal{R}_0 . Write $\mathcal{X}(L)^{\mathcal{R}_0}$ for the direct sum of all of the X_{s_1} . By the construction from [Zem23, Section 3], we see that $\mathcal{X}(L)^{\mathcal{R}_0}$ is homotopy equivalent to the knot Floer complex of K_2 , with twisted coefficients induced by the class $[K_1] \in H_1(S^3)$. Since $H_1(S^3) = 0$, twisting by the class of $[K_1]$ yields just the tensor product of $\mathcal{CFK}(K_2) \cong \mathcal{S}$ with $\mathbb{F}[T, T^{-1}]$. Therefore, $\mathcal{X}(L)^{\mathcal{R}_0}$ is homotopy equivalent to $\mathbb{F}[T, T^{-1}] \otimes_{\mathbb{F}} \mathcal{S}$. Since each $T^{s_1} \otimes \mathcal{S}$ lies in a different A_1 -Alexander grading, we conclude using similar reasoning to the proof of Lemma 6.7 that there is a strong deformation retraction of type- D structures from X_{s_1} to $T^{s_1} \otimes \mathcal{S}$. Furthermore, as in the proof of Lemma 6.7, the homotopy equivalence can be taken to be U -equivariant.

As in the proof of Lemma 6.7, using the above constructed strong deformation retraction, we will view $\mathcal{X}(L)$ and $\mathcal{X}^{\text{alg}}(L)$ as having the same underlying vector space, which we denote by $\mathcal{X}(L)$. We write $\delta^{1,1}$ and $\delta_{\text{alg}}^{1,1}$ for the two structure maps.

We now consider the components of the differentials which are weighted by non-unit elements of $\mathcal{R}_1^!$. Write L_{φ_+} and L_{φ_-} for the components of $\delta^{1,1}$ which are weighted by φ_+ and φ_- , respectively. The structure relation

$$(\delta^{1,1})^2 + \mu_0 \otimes \text{id} \otimes 1$$

(where $\mu_0 = \varphi_+ \varphi_- + \varphi_- \varphi_+$) implies that $L_{\varphi_+} \circ L_{\varphi_-} \simeq \text{id}$ and $L_{\varphi_-} \circ L_{\varphi_+} \simeq \text{id}$, as type- D endomorphisms of X_{s_1} . In particular, L_{φ_+} gives a homotopy equivalence from $T^s \otimes \mathcal{S}$ to $T^{s+1} \otimes \mathcal{S}$, and similarly for L_{φ_-} . Since L_{φ_+} and L_{φ_-} both preserve the $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ -bigrading on \mathcal{S} , they must be equal to the identity map by Lemma 4.6.

Since $\mathcal{R}_1^! \mathcal{X}(L)^{\mathcal{R}_0}$ is assumed to be U -equivariant, the only other weight one monomials appearing in $\delta^{1,1}$ consist of the component $\theta \otimes \text{id} \otimes U$ which occurs on each generator.

We now claim that there are no components of $\delta^{1,1}$ which are weighted by any monomials $a \in \mathcal{R}_1^!$ which have weight greater than 1. If $a \in \mathcal{R}_1^!$ is a product of φ_+ and φ_- which contains n factors, then write L_a for the component of $\delta^{1,1}$ which is weighted by a . We observe that L_a shifts the $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ -grading by $(n-1, n-1)$. (It has the same grading as $\delta_{n+1}^1(T^{\pm 1}, T^{\pm 1}, \dots, T^{\pm 1}, -)$ on ${}_{\mathcal{K}} \mathcal{X}(L)^{\mathcal{K}}$.) We assume by induction that $\delta^{1,1}$ has no weight j terms for $2 \leq j \leq n-1$. If a has weight n , then one verifies easily that L_a is a chain map (when viewed as a map from \mathcal{S} to \mathcal{S}). Lemma 4.7 implies that $L_a = 0$. Proceeding by induction we obtain a U -equivariant homotopy equivalence $\mathcal{R}_1^! \mathcal{X}(L)^{\mathcal{R}_0} \simeq \mathcal{R}_1^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_0}$, completing the proof. \square

6.2.3. *Idempotents $(0, 1)$ and $(1, 1)$.* We state the following result:

Lemma 6.9. *If $\mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_1}$ is U -equivariant then there is a U -equivariant homotopy equivalence $\mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_1} \simeq \mathcal{R}_0^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_1}$. The same statement holds for $\mathcal{R}_1^! \mathcal{X}(L)^{\mathcal{R}_1}$.*

The proofs of the above statements are not substantially different than the proofs of Lemma 6.7 and 6.8, so we leave them to the reader.

6.3. The length 1 differentials. Using the isomorphisms of the complexes at each idempotent, proven in Lemmas 6.7, 6.8 and 6.9, we know that ${}_{\mathcal{K}}\mathcal{X}(L)^{\mathcal{K}}$ is U -equivariantly homotopy equivalent to a complex obtained by summing over the complexes of ${}_{\mathcal{K}}\mathcal{X}^{\text{alg}}(L)^{\mathcal{K}}$ at each idempotent, and then adding some idempotent shifting differentials.

We write $\Phi^{\pm K_1}$, $\Phi^{\pm K_2}$, and $\Phi^{\pm K_1, \pm K_2}$ for the idempotent shifting differentials from $\mathcal{X}(L)$. Here, Φ^{K_1} denotes the components of $\delta^{1,1}$ which are weighted by a multiple of s (on the left), but not by a multiple of σ or τ (on the right). Similarly, Φ^{-K_1} denotes the components of $\delta^{1,1}$ which are weighted by a multiple of t on the left, but not by a multiple of σ or τ on the right. The map Φ^{K_2} denotes the component of $\delta^{1,1}$ which is weighted by a multiple of σ on the right, but not s or t on the left. The map Φ^{-K_2} is similar. The map Φ^{K_1, K_2} is the component of $\delta^{1,1}$ which is weighted by a multiple of s on the left and σ on the right. The other $\Phi^{\pm K_1, \pm K_2}$ are defined similarly.

We write $\Phi_{\text{alg}}^{\pm K_1}$, $\Phi_{\text{alg}}^{\pm K_2}$ and $\Phi_{\text{alg}}^{\pm K_1, \pm K_2}$ for the analogous idempotent shifting differentials from $\mathcal{X}^{\text{alg}}(L)$.

We recall, as in Proposition 6.5, that we are working with a U -equivariant model for ${}_{\mathcal{K}}\mathcal{X}(L)^{\mathcal{K}}$. This assumption simplifies a number of the arguments, but is only essential for the map from idempotent $(0, 0)$ to $(1, 1)$.

6.3.1. Differentials from idempotent $(0, 0)$ to $(1, 0)$.

Lemma 6.10. *The maps $\Phi^{K_1}, \Phi_{\text{alg}}^{K_1}: {}_{\mathcal{R}_0}\mathcal{X}(L)^{\mathcal{R}_0} \rightarrow {}_{\mathcal{R}_1}\mathcal{X}(L)^{\mathcal{R}_0}$ are U -equivariantly chain homotopic. Similarly Φ^{-K_1} and $\Phi_{\text{alg}}^{-K_1}$ are U -equivariantly chain homotopic.*

Remark 6.11. In the statement, we are viewing $\mathcal{R}_0^!$ and $\mathcal{R}_1^!$ as being subalgebras of $\mathcal{K}^!$, and therefore we can view both ${}_{\mathcal{R}_0}\mathcal{X}(L)^{\mathcal{R}_0}$ and ${}_{\mathcal{R}_1}\mathcal{X}(L)^{\mathcal{R}_0}$ as type- DD modules over $\mathcal{K}^!$ and \mathcal{R}_0 . The claim is that Φ^{K_1} and $\Phi_{\text{alg}}^{K_1}$ are chain homotopic as morphisms of type- DD modules, when viewed in this way.

Proof. Write L_s and L_t for the components of Φ^{K_1} and Φ^{-K_1} which are weighted by s and t , respectively. Write L_s^{alg} and L_t^{alg} for the corresponding components of $\Phi_{\text{alg}}^{K_1}$ and $\Phi_{\text{alg}}^{-K_1}$. We can view these as type- D morphisms from \mathcal{C}_{s_1} to \mathcal{S} . From the structure relations for $\delta^{1,1}$ and $\delta_{\text{alg}}^{1,1}$, it is straightforward to check that $L_s, L_t, L_s^{\text{alg}}$ and L_t^{alg} are chain maps.

The maps L_s and L_s^{alg} are chain maps from \mathcal{C}_{s_1} to \mathcal{S} which preserve the $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ grading modulo 2. Since Φ^{K_1} induces a quasi-isomorphism $\mathcal{C}_{s_1} \rightarrow \mathcal{S}$ for $s_1 \gg 0$ (compare [MO10, Lemma 10.1]), it cannot be zero on homology for any s_1 . By assumption, $\Phi_{\text{alg}}^{K_1}$ has this property, and has the same grading as Φ^{K_1} . By Lemma 4.2, we conclude that $L_s \simeq L_s^{\text{alg}}$. Let h_{s_1} be a choice of homotopy. We define a morphism of DD -bimodules $h: {}_{\mathcal{R}_0}\mathcal{X}(L)^{\mathcal{R}_0} \rightarrow {}_{\mathcal{R}_1}\mathcal{X}(L)^{\mathcal{R}_0}$ by sending $\mathbf{x} \in \mathcal{C}_{s_1}$ to $s \otimes h_{s_1}(\mathbf{x})$. By replacing Φ^{K_1} with $\Phi^{K_1} + \partial(h)$ is a chain map with the same properties, we may assume that $L_s = L_s^{\text{alg}}$. (Here, we are writing $\partial(h)$ for the type- DD morphism differential applied to h).

We now consider the component of Φ^{K_1} which is weighted by zs . We write L_{zs} for this map. We can decompose this as a sum $L_{zs}^{01} + L_{zs}^{10}$, where L_{zs}^{ij} maps algebraic grading j to algebraic grading i . In our definition of $\mathcal{X}^{\text{alg}}(L)$, we may take the zs component of the differential to be L_{zs}^{10} .

We now show how to eliminate the L_{zs}^{01} term of Φ^{K_1} via a chain homotopy.

For a fixed value $s_1 \in \text{lk}(K_1, K_2)/2 + \mathbb{Z}$, we will write $L_{zs;s_1}^{01} : \mathcal{C}_{s_1} \rightarrow \mathcal{S}$ for the above map. Firstly, for all large s_1 , we know that $L_s : \mathcal{C}_{s_1} \rightarrow \mathcal{S}$ is an isomorphism, and also that $L_z : \mathcal{C}_{s_1} \rightarrow \mathcal{C}_{s_1+1}$ is an isomorphism. We have

$$(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})(L_{zs;s_1}) = (\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})(L_s) + (\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})(L_z) + (1, 1).$$

Identifying \mathcal{C}_{s_1} and \mathcal{S} via $L_s \circ L_z$, we may view $L_{zs;s_1}^{01}$ as an endomorphism of \mathcal{S} which increases the $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ grading by $(1, 1)$. It is not hard to see that $L_{zs;s_1}^{01}$ is a chain map, so Lemma 4.7 implies that $L_{zs;s_1}^{01} = 0$ for $s_1 \gg 0$.

In order to eliminate $L_{zs;s_1}^{01}$ for other values of s_1 , we now define a map $j : \mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_0} \rightarrow \mathcal{R}_1^! \mathcal{X}(L)^{\mathcal{R}_0}$. On \mathcal{C}_{s_1} , we set j to be

$$\sum_{t_1 \geq s_1} zs \otimes T^{s_1 - \ell/2} \otimes L_{zs,t_1}^{01} \circ (L_z)^{t_1 - s_1}.$$

In detail, this maps \mathcal{C}_{s_1} to $T^{s_1 - \ell/2} \mathcal{S}$. The sum is finite because we have already arranged for L_{zs,t_1}^{01} to be zero if $t_1 \gg 0$. Also, j maps \mathcal{C}_{s_1} to the same copy of \mathcal{S} as the map L_s . It is straightforward to see that

$$\partial(j) = L_{zs}^{01}.$$

Adding this homotopy to Φ^{K_1} , we may therefore assume that the s and zs coefficients of Φ^{K_1} coincide with those of $\Phi_{\text{alg}}^{K_1}$. Since we assume that $\mathcal{K}^! \mathcal{X}(L)^{\mathcal{K}}$ is a U -equivariant model, there cannot be any θs or $\theta s \varphi_+$ weighted summands, so we conclude that our original Φ^{K_1} is chain homotopic to $\Phi_{\text{alg}}^{K_1}$.

The proof for Φ^{-K_1} is identical, so the proof is complete. \square

6.3.2. Differentials from idempotent $(0, 0)$ to $(0, 1)$.

Lemma 6.12. *The maps $\Phi^{K_2}, \Phi_{\text{alg}}^{K_2} : \mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_0} \rightarrow \mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_1}$ are U -equivariantly chain homotopic. Similarly Φ^{-K_2} and $\Phi_{\text{alg}}^{-K_2}$ are U -equivariantly chain homotopic.*

Proof. We focus on constructing a chain homotopy $\Phi^{K_2} \simeq \Phi_{\text{alg}}^{K_2}$.

We can view the map Φ^{K_2} as being induced by a map

$$\Phi^{K_2} : \mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_0} \boxtimes_{\mathcal{R}_0} [\phi^\sigma]^{\mathcal{R}_1} \rightarrow \mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_1}$$

where $\phi^\sigma : \mathcal{R}_0 \rightarrow \mathcal{R}_1$ is the natural algebra morphism described in Equation (3.3), and $\mathcal{R}_0[\phi^\sigma]^{\mathcal{R}_1}$ denotes the induced DA -bimodule. The correspondence between ϕ^{K_2} and Φ^{K_2} is as follows. If there is a generator \mathbf{x} and $\Phi^{K_2}(\mathbf{x})$ has a summand $a \otimes \mathbf{y} \otimes U^i T^j \sigma$, then we view $\phi^{K_2}(\mathbf{x})$ as having a component $a \otimes \mathbf{y} \otimes U^i T^j$.

By construction of the link surgery formula, the map ϕ^{K_2} is a homotopy equivalence. Therefore, Φ^{K_2} and $\Phi_{\text{alg}}^{K_2}$ must differ by post-composition with a grading preserving homotopy automorphism of $\mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_1}$. It suffices therefore to show that all grading preserving, U -equivariant homotopy automorphisms of $\mathcal{R}_0^! \mathcal{X}_{\text{alg}}(L)^{\mathcal{R}_1}$ are chain homotopic to the identity. We suppose that F is such a homotopy automorphism. If $a \in \mathcal{R}_0^!$, we write F_a for the component of F which is weighted by a .

In each Alexander grading $s_1 \in \mathbb{Z}$, $\mathcal{R}_0^! \mathcal{X}_{\text{alg}}(L)^{\mathcal{R}_1}$ contains a single generator, which we will denote \mathbf{y}_{s_1} .

If F is a grading preserving homotopy automorphism, then F_1 must be an isomorphism, since there are no $\mathcal{R}_0^!$ -weight 0 components of $\delta^{1,1}$ pointing to or from \mathbf{y}_{s_1} . Consequently, F_1 sends \mathbf{y}_{s_1} to $\mathbf{y}_{s_1} \otimes 1$ for all s_1 .

Next, we observe that F_z and F_w shift the $\text{gr}_{\mathbf{w}}$ -grading by ± 1 and hence must vanish since $\mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_1}$ is supported in only even $\text{gr}_{\mathbf{w}}$ -gradings.

We now consider F_{wz} and F_{zw} . By considering the wzw coefficient of the relation $\partial(\Phi^K) = 0$, we see that

$$F_{wz} \circ L_z + L_z \circ F_{zw} = \partial(F_{zwz}).$$

In particular, the map F_{zw} is non-zero on \mathbf{y}_{s_1} if and only if F_{wz} is non-zero on \mathbf{y}_{s_1+1} .

Note that since $L_z \circ L_w = \text{id} \otimes U$, one of $L_z(\mathbf{y}_{s_1})$ and $L_w(\mathbf{y}_{s_1+1})$ must be weighted by 1 and the other by U . For each $s_1 \in \mathbb{Z}$, we will define $E(s_1) \subseteq \{-1, 1\}$, as follows.

- (1) We declare $-1 \in E(s_1)$ if and only if $F_{wz}(\mathbf{y}_{s_1})$ is non-zero and $L_z(\mathbf{y}_{s_1-1})$ is weighted by 1.
- (2) We declare $1 \in E(s_1)$ if and only if $F_{zw}(\mathbf{y}_{s_1})$ is non-zero and $L_w(\mathbf{y}_{s_1+1})$ is weighted by 1.

Note that since F preserves the $(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}})$ -bigrading as well as the Alexander bigrading, the maps F_{wz} and F_{zw} can only have components whose \mathcal{R}_1 factor is $1 \in \mathcal{R}_1$.

We now define a homotopy of j as follows. If $-1 \in E(s_1)$, then we declare $j(\mathbf{y}_{s_1})$ to have a summand of $w \otimes \mathbf{y}_{s_1-1} \otimes 1$. If $1 \in E(s_1)$, then we declare $j(\mathbf{y}_{s_1})$ to have a summand of $z \otimes \mathbf{y}_{s_1+1} \otimes 1$. (If $E(s_1) = \{-1, 1\}$, we declare $j(\mathbf{y}_s)$ to be a sum of the above two elements).

One checks easily that

$$\partial(j) = wz \otimes F_{wz} + zw \otimes F_{zw}.$$

Therefore we may assume, after chain homotopy, that F_{wz} and F_{zw} are zero. We illustrate in Figure 6.1 the situation that $E(s_1) = \{1, -1\}$.

From here, we proceed by induction to remove the summands of F which are weighted by monomials of higher length. By the same grading argument as above, there can never be any summands weighted by monomials of the form $wz \cdots wz$ or $zw \cdots zw$ (i.e. monomials of odd length). The argument used above to eliminate summands weighted by wz or zw extends without substantial change to eliminate summands weighted by monomials of even length greater than 2 (i.e. $wz \cdots zw$ and $zw \cdots wz$). Since F is assumed to be U -equivariant, there are no components weighted by a multiple of θ . We have thus shown that F is chain homotopic to the identity, so the proof is complete. \square

6.3.3. Differentials from idempotent $(1, 0)$ to $(1, 1)$ and from $(0, 1)$ to $(1, 1)$. We now state the following lemmas:

Lemma 6.13.

- (1) The maps $\Phi^{K_2}, \Phi_{\text{alg}}^{K_2} : \mathcal{R}_1^! \mathcal{X}(L)^{\mathcal{R}_0} \rightarrow \mathcal{R}_1^! \mathcal{X}(L)^{\mathcal{R}_1}$ are U -equivariantly chain homotopic. Similarly Φ^{-K_2} and $\Phi_{\text{alg}}^{-K_2}$ are U -equivariantly chain homotopic.
- (2) The maps $\Phi^{K_1}, \Phi_{\text{alg}}^{K_1} : \mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_1} \rightarrow \mathcal{R}_1^! \mathcal{X}(L)^{\mathcal{R}_1}$ are U -equivariantly chain homotopic. Similarly Φ^{-K_1} and $\Phi_{\text{alg}}^{-K_1}$ are U -equivariantly chain homotopic.

The proof of the above lemma follows from identical reasoning as the proofs of Lemma 6.10 and 6.12, so we leave the details to the reader.

FIGURE 6.1. The homotopy j (dashed arrows) which eliminates wz and zw weighted arrows of F (solid arrows) when $E(s_1) = \{-1, 1\}$.

6.4. The length 2 differentials. We now analyze the length 2 differentials. The length 2 differential of the surgery complex decomposes as a sum of four maps, one for each orientation on L . The map $\Phi^{K_1 \cup K_2}$ (positive orientation on both components) increases the $\text{gr}_{\mathbf{w}}$ grading by 1. For an arbitrary orientation on L , denoted \vec{L} , if we let $\mathbf{p} \subseteq \{w_1, w_2, z_1, z_2\}$ contain one basepoint from each of K_1 and K_2 , and furthermore contain z_i if and only if \mathbf{o} is positively oriented on K_i (and contain z_i otherwise), then the map $\Phi^{\vec{L}}$ increases $\text{gr}_{\mathbf{p}}$ by 1 (see [Zem21, Lemma 6.4 (1)]).

Lemma 6.14. *Let L be a 2-component L-space link and suppose that ${}^{\kappa!}\mathcal{X}(L)^{\kappa}$ is a U -equivariant model of the link surgery complex for L . If $F: {}^{\mathcal{R}_0!}\mathcal{X}(L)^{\mathcal{R}_0} \rightarrow {}^{\mathcal{R}_1!}\mathcal{X}(L)^{\mathcal{R}_1}$ is a U -equivariant chain map which is weighted by multiples of s and σ , and which has $+1$ $\text{gr}_{\mathbf{w}}$ -grading and the same Alexander grading shift as $\Phi^{K_1 \cup K_2}$, then F is null-homotopic. The same statement holds for the other orientations on $K_1 \cup K_2$, as long as the $\text{gr}_{\mathbf{w}}$ grading is replaced with the $\text{gr}_{\mathbf{p}}$ grading, where $\mathbf{p} \subseteq \{w_1, z_1, w_2, z_2\}$ is as above.*

Proof. As in the proof of Lemma 6.12, we can interpret the map F in the statement as a chain map from

$${}^{\mathcal{R}_0!}\mathcal{X}(L)^{\mathcal{R}_0} \boxtimes_{{}^{\mathcal{R}_0}}[\phi^{\sigma}]^{\mathcal{R}_1} \rightarrow {}^{\mathcal{R}_1!}\mathcal{X}(L)^{\mathcal{R}_1}.$$

The left hand side is homotopy equivalent (U -equivariantly) to ${}^{\mathcal{R}_0!}\mathcal{X}(L)^{\mathcal{R}_1}$, and so we can view the map F instead as a map

$$F: {}^{\mathcal{R}_0!}\mathcal{X}(L)^{\mathcal{R}_1} \rightarrow {}^{\mathcal{R}_1!}\mathcal{X}(L)^{\mathcal{R}_1}.$$

Write \mathbf{y}_{s_1} for the generators of ${}^{\mathcal{R}_0!}\mathcal{X}(L)^{\mathcal{R}_1}$ and write $T^{s_1}\mathbf{e}$ for the generators of ${}^{\mathcal{R}_1!}\mathcal{X}(L)^{\mathcal{R}_1}$. The only possible components of the map F are to send \mathbf{y}_{s_1} to $zs \otimes T^{s_1+\delta+1}\mathbf{e} \otimes U^{H_{K_1}(s_1)-1}$ where δ is some fixed Alexander grading shift. (Components weighted by s are impossible since a shift in the Maslov grading by $+1$ would be impossible since all generators have even $\text{gr}_{\mathbf{w}}$ grading; components weighted by θs or $\theta s\varphi_+$ are impossible because we have assumed that F is U -equivariant). Since δ is fixed, and the module ${}^{\mathcal{R}_1!}\mathcal{X}(L)^{\mathcal{R}_1}$ has a translation action which shifts this Alexander grading by 1 but preserves the Maslov grading, we can assume that $\delta = 0$, for convenience.

Write $\epsilon(s_1) \in \mathbb{Z}/2$ for the coefficient of this component in F . (I.e. set $\epsilon(s_1) = 1$ if and only if $F(\mathbf{y}_{s_1})$ is non-zero). That is, say that

$$F(\mathbf{y}_{s_1}) = \epsilon(s_1) \cdot zs \otimes T^{s_1+1} \mathbf{e} \otimes U^{H_{K_1}(s_1)-1}. \quad (6.3)$$

We observe firstly that $\epsilon(s_1) = 0$ for $s_1 \gg 0$. This is because $H_{K_1}(s_1) = 0$ for $s_1 \gg 0$, and so the above equation would involve negative powers of U , which is prohibited. In fact, we see that $\epsilon(s_1) = 0$ if $H_{K_1}(s_1) = 0$.

We now define our homotopy by the equation

$$j(\mathbf{y}_{s_1}) = \left(\sum_{t_1 \geq s_1} \epsilon(t_1) \right) s \otimes T^{s_1} \mathbf{e} \otimes U^{H_{K_1}(s_1)-1}.$$

It is straightforward to see that this homotopy satisfies $\partial(j) = F$.

The proof for other orientations on L carries through *mutatis mutandis*. \square

Remark 6.15. The above lemma is false if we omit “ U -equivariant” from the statement. For example, we may take $\Phi^{K_1} \circ \Phi^{K_2}$ and multiply the $\mathcal{K}^!$ entries by θ .

6.5. Proof of Proposition 6.1. We now summarize our proof that $\mathcal{K}^! \mathcal{X}(L)^\mathcal{K} \simeq \mathcal{K}^! \mathcal{X}^{\text{alg}}(L)^\mathcal{K}$.

Proof of Proposition 6.1. The complex $\mathcal{K}^! \mathcal{X}(L)^\mathcal{K}$ decomposes as a hypercube of type- DD bimodules:

$$\begin{array}{ccccc} & \mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_0} & \xrightarrow{\Phi^{K_2} + \Phi^{-K_2}} & \mathcal{R}_0^! \mathcal{X}(L)^{\mathcal{R}_1} & \\ & \downarrow \Phi^{K_1} + \Phi^{-K_1} & \searrow \Phi^{\pm K_1, \pm K_2} & \downarrow \Phi^{K_1} + \Phi^{-K_1} & \\ \mathcal{K}^! \mathcal{X}(L)^\mathcal{K} = & & & & \\ & \mathcal{R}_1^! \mathcal{X}(L)^{\mathcal{R}_0} & \xrightarrow{\Phi^{K_2} + \Phi^{-K_2}} & \mathcal{R}_1^! \mathcal{X}(L)^{\mathcal{R}_1} & \end{array} \quad (6.4)$$

By assumption, all of these complexes and maps are U -equivariant. The complex $\mathcal{K}^! \mathcal{X}^{\text{alg}}(L)^\mathcal{K}$ decomposes similarly.

Proposition 6.5 implies that $\mathcal{K}^! \mathcal{X}(L)^\mathcal{K}$ is homotopy equivalent to a complex similar to the one in Equation (6.4), but with $\mathcal{R}_\nu^! \mathcal{X}^{\text{alg}}(L)^{\mathcal{R}_\nu}$ replacing each $\mathcal{R}_\nu^! \mathcal{X}(L)^{\mathcal{R}_\nu}$. Since the homotopy equivalences are U -equivariant, the resulting hypercube structure maps are also U -equivariant. Applying Lemmas 6.10, 6.12 and 6.13, we conclude that $\Phi^{\pm K_i} \simeq \Phi_{\text{alg}}^{\pm K_i}$, so $\mathcal{K}^! \mathcal{X}(L)^\mathcal{K}$ is homotopy equivalent to a complex that agrees with $\mathcal{K}^! \mathcal{X}^{\text{alg}}(L)^\mathcal{K}$, except possibly along its diagonal (length 2) map. Lemma 6.14 implies that any two choices of diagonal map are homotopic, which implies that the two hypercubes are homotopy equivalent, completing the proof. \square

7. RELATING THE COMPLETED AND UNCOMPLETED ALGEBRAS

There are several natural ways that we can complete $\mathcal{K}^!$:

- (1) No completions on the algebra $\mathcal{K}^!$.
- (2) Completing $\mathcal{K}^!$ with respect to the tensor weight filtration on $\mathcal{R}_0^!$.

- (3) Completing $\mathcal{K}^!$ with respect to the tensor weight filtration on $\mathcal{R}_0^!$ and $\mathcal{R}_1^!$.
- (4) Completing $\mathcal{K}^!$ with respect to the tensor weight filtration on $\mathcal{R}_1^!$.

We are interested in the first and second ways of completing the algebra. We will write $\mathcal{K}^!$ and $\mathcal{K}^!$ for these two manners of completing the algebra. We do not have any applications of the third or fourth, so we will not consider it in this paper.

Proposition 7.1. *There is an A_∞ -equivalence of categories between $\mathcal{K}^! \text{Mod}$ and $\mathcal{K}^! \text{Mod}$.*

Remark 7.2. Conceptually, the proof is related to the fact that $\mathcal{R}_0^!$ and $\mathcal{R}_0^!$ have homology equal to the exterior algebra on two generators. In fact, there is an A_∞ -algebra $\mathcal{K}_\infty^!$ which is quasi-equivalent to both $\mathcal{K}^!$ and $\mathcal{K}^!$. The algebra $\mathcal{K}_\infty^!$ has in idempotent $(0, 0)$ the exterior algebra on two generators in place of $\mathcal{R}_0^!$. See [Zem25, Lemma 3.3].

Proof. We will define A_∞ -algebra morphisms ϕ and ι and consider the induced bimodules ${}^{\mathcal{K}^!}[\phi]_{\mathcal{K}^!}$ and ${}^{\mathcal{K}^!}[\iota]_{\mathcal{K}^!}$ (see [LOT15, Definition 2.2.48]). We will prove that $[\phi] \boxtimes [\iota]$ and $[\iota] \boxtimes [\phi]$ are both homotopy equivalent to the identity functors. Furthermore, these bimodules and the morphisms between them will be bounded as DA -bimodules (in the sense that $\delta_n^1 = 0$ if $n \gg 0$).

The morphism ι is given by the inclusion map $\iota: \mathcal{K}^! \rightarrow \mathcal{K}^!$. That is, we have ι_1 is the inclusion and $\iota_j = 0$ for $j > 1$.

The morphism ϕ is more complicated. We begin by defining the map $\phi_1: \mathcal{K}^! \rightarrow \mathcal{K}^!$. We pick an integer $N \geq 4$. (The choice of N is not important for our proof, so we could pick $N = 4$).

If $a \in \mathbf{I}_0 \cdot \mathcal{K}^1 \cdot \mathbf{I}_0$ is a monomial, we define $\text{wt}_\theta(a) \in \{0, 1\}$ to be 0 if a is not a multiple of θ , and to be 1 otherwise. We write $\text{wt}(a)$ for the number of factors of a . (E.g. $\text{wt}(wz) = 2$, $\text{wt}(\theta wz wz) = 5$). We write $\text{wt}_+(a) = \text{wt}(a) + \text{wt}_\theta(a)$. Notice that wt_+ is preserved by μ_1 and μ_2 . We set

$$\phi_1(a) = \begin{cases} a & \text{if } \text{wt}_+(a) \leq N \\ 0 & \text{otherwise.} \end{cases}$$

We define ϕ_1 to be the identity on all monomials in idempotent $(0, 1)$ or $(1, 1)$. If a and b are monomials in idempotent $(0, 0)$, we set

$$\phi_2(a, b) = \begin{cases} (ab)'\theta & \text{if } \text{wt}_+(ab) > N, \text{wt}_+(a) \leq N, \text{wt}_+(b) \leq N \\ 0 & \text{otherwise.} \end{cases}$$

In the above $(ab)'$ denotes the monomial obtained from ab by reducing wt by 2 (by removing the last two non- θ symbols from ab) while preserving wt_θ . For example, $(wz wz wz) = wz wz$ and $(zw zw \theta)' = zw \theta$. We set $\phi_2(a, b)$ to be zero if a or b is not in idempotent $(0, 0)$.

The compatibility condition is proven as follows. The compatibility condition with one input amounts to the claim that ϕ_1 is a chain map, which is easy to verify. The compatibility condition on two inputs, a and b , is proven as follows. The compatibility condition amounts to the claim that

$$\phi_1(ab) + \phi_1(a)\phi_1(b) + \mu_1\phi_2(a, b) + \phi_2(\mu_1 a, b) + \phi_2(a, \mu_1 b) = 0.$$

Note that the claim is only non-trivial when $ab \neq 0$. The proof of this relation breaks into several cases:

- (1) ($\text{wt}_+(a) \leq N$, $\text{wt}_+(b) \leq N$ and $\text{wt}_+(ab) \leq N$) In this case, $\phi_2(a, b) = \phi_2(\mu_1 a, b) = \phi_2(a, \mu_1 b) = 0$ and the compatibility condition is straightforward to verify.
- (2) ($\text{wt}_+(a) > N$ or $\text{wt}_+(b) > N$) In this case, $\phi_1(ab) + \phi_1(a)\phi_1(b) = 0$, and also $\phi_2(a, b) = \phi_2(\mu_1 a, b) = \phi_2(a, \mu_1 b) = 0$, so the compatibility condition follows.
- (3) ($\text{wt}_+(a) \leq N$, $\text{wt}_+(b) \leq N$ and $\text{wt}_+(ab) > N$) In this case, $\phi_1(a)\phi_1(b) + \phi_1(ab) = ab$. If $\text{wt}_\theta(a) = \text{wt}_\theta(b) = 0$, then $\mu_1\phi_2(a, b) = ab$ while $\phi_2(\mu_1 a, b) = \phi_2(a, \mu_1 b) = 0$, so the compatibility condition follows. If $\text{wt}_\theta(a) = 1$ while $\text{wt}_\theta(b) = 0$, then $\mu_1\phi_2(a, b) = \phi_2(a, \mu_1 b) = 0$ while $\phi_2(\mu_1 a, b) = ab$, so the compatibility condition follows. The case that $\text{wt}_\theta(a) = 0$ while $\text{wt}_\theta(b) = 1$ is similar. Finally, if $\text{wt}_\theta(a) = \text{wt}_\theta(b) = 1$, then $ab = \mu_1\phi_2(a, b) = \phi_2(\mu_1 a, b) = \phi_2(a, \mu_1 b) = 0$, so the compatibility condition follows.

We now consider the compatibility condition with three or more inputs. We focus on three inputs since the case of more than three inputs follows from similar reasoning. Similar to the previous cases, the condition is only non-trivial if all inputs are in $\mathbf{I}_0 \cdot \mathcal{R}_0^! \cdot \mathbf{I}_0$. Let $F: R_0^! \otimes R_0^! \otimes R_0^! \rightarrow R_0^!$ be the map

$$F(a, b, c) = \mu_2(\phi_2(a, b), \phi_1(c)) + \mu_2(\phi_1(a), \phi_2(b, c)) + \phi_2(\mu_2(a, b), c) + \phi_2(a, \mu_2(b, c)).$$

Since $\phi_3 = 0$, this is the sum of all of the terms of the compatibility condition. The compatibility conditions for one and two inputs imply that F is a chain map (where we equip the domain with the differential $\mu_1 \otimes \mathbb{I}^2 + \mathbb{I} \otimes \mu_1 \otimes \mathbb{I} + \mathbb{I}^2 \otimes \mu_1$). Furthermore, wt_θ gives a grading on both the domain and the codomain of F which F increases by 1. Schematically, if we write $(C_3 \rightarrow C_2 \rightarrow C_1 \rightarrow C_0)$ for the domain of F (where the subscript indicates the wt_θ -grading) and $(E_1 \rightarrow E_0)$ denotes the codomain, then F induces a map from C_1 to E_0 , and F vanishes on C_3 , C_2 and C_1 . Since F is a chain map and the differential vanishes on E_0 , we have that $\mu_1 \circ F$ vanishes. However $R_0^!$ has trivial homology in wt_θ -grading 1, so $\mu_1: E_1 \rightarrow E_0$ is injective, and therefore $F = 0$. Therefore the compatibility condition is satisfied. A similar argument shows that all of the compatibility conditions with more inputs also are satisfied.

We now construct morphisms of bimodules

$$\mathcal{K}^![\phi]_{\mathcal{K}^!} \boxtimes \mathcal{K}^![\iota]_{\mathcal{K}^!} \xrightleftharpoons[g]{f} \mathcal{K}^! \mathbb{I}_{\mathcal{K}^!}$$

which satisfy $g \circ f = \mathbb{I}$ and $f \circ g = \mathbb{I}$.

We define f as follows. We set $f_1^1(1) = 1 \otimes 1$. We set f_2^1 to vanish except on idempotent $(0, 0)$. We set $f_2^1(1, a)$ to vanish unless $\phi_1(a) = 0$ (i.e. $\text{wt}_+(a) > N$) and $\text{wt}_\theta(a) = 0$. In this case, we set $f_2^1(1, a) = a' \theta \otimes 1$, where a' again means the monomial obtained by reducing the $\text{wt}(a)$ by 2 while preserving $\text{wt}_\theta(a)$.

One easily checks that f is a morphism of bimodules. We define the map g using the same formula as f . It is easy to check that both $f \circ g$ and $g \circ f$ are equal to the identity.

Next, we construct an isomorphism between $\mathcal{K}^![\iota]_{\mathcal{K}^!} \boxtimes \mathcal{K}^![\phi]_{\mathcal{K}^!}$ and $\mathcal{K}^! \mathbb{I}_{\mathcal{K}^!}$. We observe that the structure maps of $\mathcal{K}^![\iota]_{\mathcal{K}^!} \boxtimes \mathcal{K}^![\phi]_{\mathcal{K}^!}$ have the same formula as those from $\mathcal{K}^![\phi]_{\mathcal{K}^!} \boxtimes \mathcal{K}^![\iota]_{\mathcal{K}^!}$. Furthermore, the bimodule maps f and g we defined above reduce the weight filtration by at most 1, and hence they induce well defined maps over the completed algebra $\mathcal{K}^!$. In particular, we also conclude that $\mathcal{K}^![\iota]_{\mathcal{K}^!} \boxtimes \mathcal{K}^![\phi]_{\mathcal{K}^!}$ and $\mathcal{K}^! \mathbb{I}_{\mathcal{K}^!}$ are isomorphic, completing the proof. \square

Example 7.3. The complex $\mathbf{x} \xrightarrow{1+wz} \mathbf{y}$ is contractible in $\mathcal{R}^b\mathbf{Mod}$, because we can define a null-homotopy H of the identity by $H(\mathbf{y}) = \sum_{n=0}^{\infty} (wz)^n \otimes \mathbf{x}$. We observe that this complex is also contractible in $\mathcal{R}^b\mathbf{Mod}$ because we can instead take $H(\mathbf{y}) = (1 + wz) \otimes \mathbf{x} + wz\theta \otimes \mathbf{y}$, $H(\mathbf{x}) = wz\theta \otimes \mathbf{x}$.

As a consequence, we obtain the main theorem:

Theorem 7.4. *If \mathcal{A} is an arc system so that ${}^{\mathcal{K}^!}\mathcal{X}(L; \mathcal{A})^{\mathcal{K}}$ is U -equivariant, then there is a homotopy equivalence of type-DD bimodules ${}^{\mathcal{K}^!}\mathcal{X}(L; \mathcal{A})^{\mathcal{K}} \simeq {}^{\mathcal{K}^!}\mathcal{X}^{\text{alg}}(L)^{\mathcal{K}}$.*

Proof. Proposition 6.1 implies that there is an equivalence after over the completed algebra $\mathcal{K}^!$. Proposition 7.1 now implies that this equivalence holds also on the uncompleted algebras $\mathcal{K}^!$. \square

By tensoring the above equivalence with the dualizing bimodule ${}_{\mathcal{K}}[\mathcal{T}r]_{\mathcal{K}^!}$, we obtain the statement in Theorem 1.2.

8. EXAMPLES

In this section, we illustrate the construction of the bimodules ${}^{\mathcal{K}^!}\mathcal{X}^{\text{alg}}(L)^{\mathcal{K}}$ when L is the positively clasper Whitehead link $\text{Wh}_+ = K_1 \cup K_2$, equipped with framing $(\lambda_1, \lambda_2) = (0, 0)$. We first describe the bimodule ${}^{\mathcal{K}^!}\mathcal{X}^{\text{alg}}(\text{Wh}_+)^{\mathcal{K}}$, and then we compute the surgery complex of the knot $W \subseteq S^1 \times S^2$ obtained by performing 0-surgery to one component of Wh_+ .

8.1. The bimodule ${}^{\mathcal{K}^!}\mathcal{X}^{\text{alg}}(\text{Wh}_+)^{\mathcal{K}}$. In this section, we compute the bimodule ${}^{\mathcal{K}^!}\mathcal{X}^{\text{alg}}(\text{Wh}_+)^{\mathcal{K}}$. The $(0, 0)$ and $(1, 0)$ idempotents of ${}_{\mathcal{K}}\mathcal{X}^{\text{alg}}(\text{Wh}_+)^{\mathcal{K}}$ are described in [CZZ24, Section 6.2] (see also [CZZ25, Section 4.1]). As described in [Zem25, Section 5.3], the description of the DD-bimodule over $(\mathcal{K}^!, \mathcal{R}_0)$ is essentially equivalent to this perspective.

In Figure 8.1, we illustrate the H -function of Wh_+ . The boxed entry represents generators of algebraic grading 0 in the $(0, 0)$ idempotent.

FIGURE 8.1. The H -function of the positively clasper Whitehead link Wh_+ .

The bimodule $\mathcal{R}_0^! \mathcal{X}(\text{Wh}_+)^{\mathcal{R}_0}$ takes the following form:

Here, $\mathbf{x}_{s_1}^j$ denote the j th generator in the staircase complex \mathcal{C}_{s_1} with the first Alexander grading $A_1 = s_1$, and we denote $\mathbf{x}_{s_1}^0$ by \mathbf{x}_{s_1} if there is only a single generator in \mathcal{C}_{s_1} . The arrows indicate the $\delta^{1,1}$ differential. Each generator has a θ -weighted arrow $\theta|U$ pointing to itself by the U -equivariant condition, which we omit from the drawing. (We will omit such arrows for other idempotents as well to simplify the drawing.)

The gradings of the generators are given by

$$\begin{aligned} (\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}}, A_1, A_2)(\mathbf{x}_0^0) &= (0, -2, 0, 1) \\ (\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}}, A_1, A_2)(\mathbf{x}_0^1) &= (-1, -1, 0, 0), \\ (\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}}, A_1, A_2)(\mathbf{x}_0^2) &= (-2, 0, 0, -1), \end{aligned}$$

and for $s_1 \neq 0$,

$$(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}}, A_1, A_2)(\mathbf{x}_{s_1}) = \begin{cases} (0, -2s_1, s_1, 0) & \text{if } s_1 > 0, \\ (2s_1, 0, s_1, 0) & \text{if } s_1 < 0. \end{cases}$$

Since K_2 is an unknot (after deleting K_1), the complex $\mathcal{S} = \mathcal{CFK}(K_2)$ is spanned by a single generator, for which we write \mathbf{x}' . The bimodule $\mathcal{R}_1^! \mathcal{X}(\text{Wh}_+)^{\mathcal{R}_0}$ therefore takes the following form:

where \mathbf{x}' is the generator of $\mathcal{CFK}(K_2)$, and K_2 is the unknot. We set

$$(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}}, A_1, A_2)(T^i \mathbf{x}') = (0, 0, i, 0).$$

The $(0, 1)$ idempotent $\mathcal{R}_0^! \mathcal{X}(\text{Wh}_+)^{\mathcal{R}_1}$ takes the following form:

Since K_1 is the unknot, we compute

$$\eta(s_1) = H_{K_1}(s_1) - H_{K_1}(s_1 + 1) = \max\{0, -s_1\}.$$

The gradings of \mathbf{y}_{s_1} are given by

$$(\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}}, A_1, A_2)(\mathbf{y}_{s_1}) = \begin{cases} (0, -2s_1, s_1, 0) & \text{if } s_1 \geq 0, \\ (2s_1, 0, s_1, 0) & \text{if } s_1 < 0. \end{cases}$$

The $(1, 1)$ idempotent $\mathcal{R}_1^1 \mathcal{X}(\text{Wh}_+) \mathcal{R}_1$ takes the following form:

$$\begin{array}{ccccccc} \cdots & \xrightarrow{\varphi_+|1} & T^{-1}\mathbf{e} & \xrightarrow{\varphi_+|1} & T^0\mathbf{e} & \xrightarrow{\varphi_+|1} & T^1\mathbf{e} & \xrightarrow{\varphi_+|1} & \cdots \\ & \nwarrow \varphi_-|1 & \nwarrow \varphi_-|1 & \nwarrow \varphi_-|1 & \nwarrow \varphi_-|1 & \nwarrow \varphi_-|1 & \nwarrow \varphi_-|1 & \nwarrow \varphi_-|1 & \end{array}$$

which is the same for every two-component L -space link in S^3 . Each generator $T^i\mathbf{e}$ has a single Maslov grading equal to 0, and has Alexander gradings $(A_1, A_2)(T^i\mathbf{e}) = (i, 0)$.

The length 1 map $\Phi^{+K_1} + \Phi^{-K_1} : \mathcal{R}_0^1 \mathcal{X}(\text{Wh}_+) \mathcal{R}_0 \rightarrow \mathcal{R}_1^1 \mathcal{X}(\text{Wh}_+) \mathcal{R}_0$ is shown below (this computation is also performed in [CZZ24, Section 6.2])

$$\begin{array}{c} \mathcal{R}_0^1 \mathcal{X}(\text{Wh}_+) \mathcal{R}_0 \quad \cdots \quad \begin{array}{c} \xrightarrow{z|U} \mathbf{x}_{-2} \xrightarrow{z|U} \mathbf{x}_{-1} \xrightarrow{z|W} \mathbf{x}_0^0 \xrightarrow{z|Z} \mathbf{x}_1 \xrightarrow{z|1} \mathbf{x}_2 \end{array} \quad \cdots \\ \downarrow \Phi^{+K_1} + \Phi^{-K_1} = \\ \mathcal{R}_1^1 \mathcal{X}(\text{Wh}_+) \mathcal{R}_0 \quad \cdots \quad \begin{array}{c} \xrightarrow{\varphi_+|1} T^{-2}\mathbf{x}' \xrightarrow{\varphi_+|1} T^{-1}\mathbf{x}' \xrightarrow{\varphi_+|1} T^0\mathbf{x}' \xrightarrow{\varphi_+|1} T^1\mathbf{x}' \xrightarrow{\varphi_+|1} T^2\mathbf{x}' \end{array} \quad \cdots \end{array}$$

The diagram shows a complex network of arrows between generators \mathbf{x}_i and \mathbf{x}'_i . The top row represents $\mathcal{R}_0^1 \mathcal{X}(\text{Wh}_+) \mathcal{R}_0$ with generators $\mathbf{x}_{-2}, \mathbf{x}_{-1}, \mathbf{x}_0^0, \mathbf{x}_1, \mathbf{x}_2$. The bottom row represents $\mathcal{R}_1^1 \mathcal{X}(\text{Wh}_+) \mathcal{R}_0$ with generators $T^{-2}\mathbf{x}', T^{-1}\mathbf{x}', T^0\mathbf{x}', T^1\mathbf{x}', T^2\mathbf{x}'$. The map $\Phi^{+K_1} + \Phi^{-K_1}$ is represented by a series of vertical arrows labeled with expressions like $s|U^2 + t|1$, $s|U + t|1$, $s|Z + t|Z$, $s|1 + t|U$, and $s|1 + t|U^2$. There are also horizontal arrows between the top row generators labeled with $z|U, z|W, z|Z, z|1$ and $w|1, w|U, w|Z, w|1$. The bottom row has horizontal arrows labeled with $\varphi_+|1$ and $\varphi_-|1$.

Next, we compute the length 1 map $\Phi^{+K_2} + \Phi^{-K_2} : \mathcal{R}_0^1 \mathcal{X}(\text{Wh}_+) \mathcal{R}_0 \rightarrow \mathcal{R}_0^1 \mathcal{X}(\text{Wh}_+) \mathcal{R}_1$ by the description in Section 5.2.2. The result is drawn in the following picture.

$$\begin{array}{c} \mathcal{R}_0^1 \mathcal{X}(\text{Wh}_+) \mathcal{R}_0 \quad \cdots \quad \begin{array}{c} \xrightarrow{z|U} \mathbf{x}_{-2} \xrightarrow{z|U} \mathbf{x}_{-1} \xrightarrow{z|W} \mathbf{x}_0^0 \xrightarrow{z|Z} \mathbf{x}_1 \xrightarrow{z|1} \mathbf{x}_2 \end{array} \quad \cdots \\ \downarrow \Phi^{+K_2} + \Phi^{-K_2} = \\ \mathcal{R}_0^1 \mathcal{X}(\text{Wh}_+) \mathcal{R}_1 \quad \cdots \quad \begin{array}{c} \xrightarrow{z|U} \mathbf{y}_{-2} \xrightarrow{z|U} \mathbf{y}_{-1} \xrightarrow{z|U} \mathbf{y}_0 \xrightarrow{z|1} \mathbf{y}_1 \xrightarrow{z|1} \mathbf{y}_2 \end{array} \quad \cdots \end{array}$$

The diagram shows a complex network of arrows between generators \mathbf{x}_i and \mathbf{y}_i . The top row represents $\mathcal{R}_0^1 \mathcal{X}(\text{Wh}_+) \mathcal{R}_0$ with generators $\mathbf{x}_{-2}, \mathbf{x}_{-1}, \mathbf{x}_0^0, \mathbf{x}_1, \mathbf{x}_2$. The bottom row represents $\mathcal{R}_0^1 \mathcal{X}(\text{Wh}_+) \mathcal{R}_1$ with generators $\mathbf{y}_{-2}, \mathbf{y}_{-1}, \mathbf{y}_0, \mathbf{y}_1, \mathbf{y}_2$. The map $\Phi^{+K_2} + \Phi^{-K_2}$ is represented by a series of vertical arrows labeled with expressions like $1|\sigma + 1|\tau$, $1|\sigma + 1|\tau$, $1|T\sigma + 1|UT\tau$, $1|UT^{-1}\sigma + 1|T^{-1}\tau$, and $1|\sigma + 1|\tau$. There are also horizontal arrows between the top row generators labeled with $z|U, z|W, z|Z, z|1$ and $w|1, w|U, w|Z, w|1$. The bottom row has horizontal arrows labeled with $z|U$ and $w|1$.

For example, we have

$$\text{gr}(R^\sigma(\mathbf{x}_0^0)) = \text{gr}(\mathbf{x}_0^0) + \text{gr}(R^\sigma) = (0, -2, 0, 1) + (0, 2, 0, 0) = (0, 0, 0, 1),$$

where $\text{gr} = (\text{gr}_{\mathbf{w}}, \text{gr}_{\mathbf{z}}, A_1, A_2)$ and \mathbf{y}_0 has grading $\text{gr} = (0, 0, 0, 0)$. Therefore,

$$R^\sigma(\mathbf{x}_0^0) = \mathbf{y}_0 \otimes T,$$

where T in the coefficient carries the grading $A_2 = 1$. This corresponds to the arrow $1|T\sigma$ from \mathbf{x}_0^0 to \mathbf{y}_0 . The rest of the components can be computed in the same manner.

Next, we compute the length 1 map $\Phi^{+K_1} + \Phi^{-K_1} : \mathcal{R}_0^1 \mathcal{X}(\text{Wh}_+)^{\mathcal{R}_1} \rightarrow \mathcal{R}_1^1 \mathcal{X}(\text{Wh}_+)^{\mathcal{R}_1}$. Since K_1 is the unknot, the 0-framed knot surgery complex ${}_{\mathcal{K}}\mathcal{X}_0(K_1)^{\mathbb{F}[U]}$ has the action

$$L_\sigma(\mathbf{y}) = L_\tau(\mathbf{y}) = \mathbf{e},$$

where \mathbf{y} (resp. \mathbf{e}) is the unique generator in the 0 (resp. 1) idempotent of ${}_{\mathcal{K}}\mathcal{X}_0(K_1)^{\mathbb{F}[U]}$. The linking number of the Whitehead link is 0. Therefore, by the description in Section 5.2.4, the length 1 map takes the following form:

$$\begin{array}{c} \mathcal{R}_0^1 \mathcal{X}(\text{Wh}_+)^{\mathcal{R}_1} \quad \cdots \quad \begin{array}{c} \xrightarrow{z|U} \mathbf{y}_{-2} \xleftarrow{w|1} \mathbf{y}_{-1} \xleftarrow{w|1} \mathbf{y}_0 \xleftarrow{w|U} \mathbf{y}_1 \xleftarrow{w|U} \mathbf{y}_2 \xleftarrow{w|U} \cdots \\ \xleftarrow{z|U} \mathbf{y}_{-1} \xleftarrow{z|U} \mathbf{y}_0 \xleftarrow{z|1} \mathbf{y}_1 \xleftarrow{z|1} \mathbf{y}_2 \xleftarrow{z|1} \cdots \end{array} \\ \downarrow \Phi^{+K_1} + \Phi^{-K_1} = \\ \mathcal{R}_1^1 \mathcal{X}(\text{Wh}_+)^{\mathcal{R}_1} \quad \cdots \quad \begin{array}{c} \xrightarrow{\varphi_+|1} T^{-2}\mathbf{e} \xleftarrow{\varphi_-|1} T^{-1}\mathbf{e} \xleftarrow{\varphi_-|1} T^0\mathbf{e} \xleftarrow{\varphi_-|1} T^1\mathbf{e} \xleftarrow{\varphi_-|1} T^2\mathbf{e} \xleftarrow{\varphi_-|1} \cdots \\ \xleftarrow{\varphi_+|1} T^{-1}\mathbf{e} \xleftarrow{\varphi_+|1} T^0\mathbf{e} \xleftarrow{\varphi_+|1} T^1\mathbf{e} \xleftarrow{\varphi_+|1} T^2\mathbf{e} \xleftarrow{\varphi_+|1} \cdots \end{array} \end{array}$$

(Vertical arrows from \mathbf{y}_{-2} to $T^{-2}\mathbf{e}$ are labeled $s|U^2 + t|1$, from \mathbf{y}_{-1} to $T^{-1}\mathbf{e}$ are $s|U + t|1$, from \mathbf{y}_0 to $T^0\mathbf{e}$ are $s|1 + t|1$, from \mathbf{y}_1 to $T^1\mathbf{e}$ are $s|1 + t|U$, and from \mathbf{y}_2 to $T^2\mathbf{e}$ are $s|1 + t|U^2$.)

Finally, we compute the length 1 map $\Phi^{+K_2} + \Phi^{-K_2} : \mathcal{R}_1^1 \mathcal{X}(\text{Wh}_+)^{\mathcal{R}_0} \rightarrow \mathcal{R}_1^1 \mathcal{X}(\text{Wh}_+)^{\mathcal{R}_1}$. Since K_2 is the unknot, the 0-framed surgery complex ${}_{\mathcal{K}}\mathcal{X}_0(K_2)^{\mathcal{K}}$ takes the form:

$$\mathbf{x}' \xrightarrow{\sigma+\tau} \mathbf{e}, \quad (8.1)$$

where \mathbf{x}' (resp. \mathbf{e}) is the unique generator in the 0 (resp. 1) idempotent of ${}_{\mathcal{K}}\mathcal{X}_0(K_2)^{\mathcal{K}}$. Then, by the description in Section 5.2.3, the length 1 map takes the following form

$$\begin{array}{c} \mathcal{R}_1^1 \mathcal{X}(\text{Wh}_+)^{\mathcal{R}_0} \quad \cdots \quad \begin{array}{c} \xrightarrow{\varphi_+|1} T^{-2}\mathbf{x}' \xleftarrow{\varphi_-|1} T^{-1}\mathbf{x}' \xleftarrow{\varphi_-|1} T^0\mathbf{x}' \xleftarrow{\varphi_-|1} T^1\mathbf{x}' \xleftarrow{\varphi_-|1} T^2\mathbf{x}' \xleftarrow{\varphi_-|1} \cdots \\ \xleftarrow{\varphi_+|1} T^{-1}\mathbf{x}' \xleftarrow{\varphi_+|1} T^0\mathbf{x}' \xleftarrow{\varphi_+|1} T^1\mathbf{x}' \xleftarrow{\varphi_+|1} T^2\mathbf{x}' \xleftarrow{\varphi_+|1} \cdots \end{array} \\ \downarrow \Phi^{+K_2} + \Phi^{-K_2} = \\ \mathcal{R}_1^1 \mathcal{X}(\text{Wh}_+)^{\mathcal{R}_1} \quad \cdots \quad \begin{array}{c} \xrightarrow{\varphi_+|1} T^{-2}\mathbf{e} \xleftarrow{\varphi_-|1} T^{-1}\mathbf{e} \xleftarrow{\varphi_-|1} T^0\mathbf{e} \xleftarrow{\varphi_-|1} T^1\mathbf{e} \xleftarrow{\varphi_-|1} T^2\mathbf{e} \xleftarrow{\varphi_-|1} \cdots \\ \xleftarrow{\varphi_+|1} T^{-1}\mathbf{e} \xleftarrow{\varphi_+|1} T^0\mathbf{e} \xleftarrow{\varphi_+|1} T^1\mathbf{e} \xleftarrow{\varphi_+|1} T^2\mathbf{e} \xleftarrow{\varphi_+|1} \cdots \end{array} \end{array}$$

(Vertical arrows from $T^{-2}\mathbf{x}'$ to $T^{-2}\mathbf{e}$ are labeled $1|\sigma + 1|\tau$, and similarly for other $T^i\mathbf{x}'$ to $T^i\mathbf{e}$.)

The length 2 maps $\Phi^{\pm K_1, \pm K_2} : \mathcal{R}_0^1 \mathcal{X}(\text{Wh}_+)^{\mathcal{R}_0} \rightarrow \mathcal{R}_1^1 \mathcal{X}(\text{Wh}_+)^{\mathcal{R}_1}$ vanish.

8.2. The Whitehead knot in $S^1 \times S^2$. We now compute the surgery complex of the Whitehead knot $W \subseteq S^1 \times S^2$ obtained by performing 0-surgery to K_1 . Using the type-AA bimodule ${}_{\mathcal{K}}[\mathcal{T}r]_{\mathcal{K}!}$ defined in [Zem25, Section 3.4], we have

$$\mathcal{X}_0(S^1 \times S^2, W)^{\mathcal{K}} \simeq \mathcal{X}_0(U)^{\mathcal{K}} \boxtimes {}_{\mathcal{K}}[\mathcal{T}r]_{\mathcal{K}!} \boxtimes {}^{\mathcal{K}!} \mathcal{X}^{\text{alg}}(\text{Wh}_+)^{\mathcal{K}}, \quad (8.2)$$

Here, U is the unknot in S^3 , with the 0-framed surgery complex ${}_{\mathcal{K}}\mathcal{X}_0(U)^{\mathcal{K}}$ shown below:

$$\mathcal{X}_0(U)^{\mathcal{K}} = (\mathbf{X}_0 \xrightarrow{\sigma+\tau} \mathbf{X}_1).$$

It is straightforward to see directly from the construction in [Zem25, Section 3.4] that the only sequence of monomials $a_1, \dots, a_n \in \mathcal{K}^!$ such that

$$m_{1|1|n}(\sigma, 1, a_1, \dots, a_n) \neq 0$$

has $n = 1$ and $a_1 = s$. The analogous claim holds for sequences that pair non-trivially with τ .

The idempotent 0 subspace of $\mathcal{X}_0(S^1 \times S^2, W)^\mathcal{K}$ is therefore given by the infinite complex

$$\begin{array}{ccccc}
 & & \mathbf{X}_0|\mathbf{x}_0^0 & & \\
 & & \uparrow W & & \\
 \cdots \mathbf{X}_0|\mathbf{x}_{-2} & \mathbf{X}_0|\mathbf{x}_{-1} & \mathbf{X}_0|\mathbf{x}_0^1 & \mathbf{X}_0|\mathbf{x}_1 & \mathbf{X}_0|\mathbf{x}_2 \cdots \\
 \downarrow 1+U^2 & \downarrow 1+U & \downarrow Z & \downarrow 1+U & \downarrow 1+U^2 \\
 \cdots \mathbf{X}_1|T^{-2}\mathbf{x}' & \mathbf{X}_1|T^{-1}\mathbf{x}' & \mathbf{X}_1|T^0\mathbf{x}' & \mathbf{X}_1|T^1\mathbf{x}' & \mathbf{X}_1|T^2\mathbf{x}' \cdots
 \end{array}$$

Idempotent 1 of the tensor product is given by

$$\begin{array}{ccccc}
 \cdots \mathbf{X}_0|\mathbf{y}_{-2} & \mathbf{X}_0|\mathbf{y}_{-1} & \mathbf{X}_0|\mathbf{y}_0 & \mathbf{X}_0|\mathbf{y}_1 & \mathbf{X}_0|\mathbf{y}_2 \cdots \\
 \downarrow 1+U^2 & \downarrow 1+U & & \downarrow 1+U & \downarrow 1+U^2 \\
 \cdots \mathbf{X}_1|T^{-2}\mathbf{e} & \mathbf{X}_1|T^{-1}\mathbf{e} & \mathbf{X}_1|T^0\mathbf{e} & \mathbf{X}_1|T^1\mathbf{e} & \mathbf{X}_1|T^2\mathbf{e} \cdots
 \end{array}$$

We note that in both idempotents $(0, 0)$ and $(1, 1)$ of \mathcal{K} , the element $1 + U^n$ is a unit if $n > 0$ since we complete \mathcal{K} with respect to the U -adic topology (see [Zem23, Section 4.2] for more on completions on \mathcal{K}). In particular, after homotopy equivalence, we may remove all of the generators except

$$\mathbf{X}_0|\mathbf{x}_0^0, \quad \mathbf{X}_0|\mathbf{x}_0^1, \quad \mathbf{X}_0|\mathbf{x}_0^2, \quad \mathbf{X}_1|T^0\mathbf{x}', \quad \mathbf{X}_0|\mathbf{y}_0, \quad \text{and} \quad \mathbf{X}_1|T^0\mathbf{e}.$$

Furthermore, using the description of Φ^{K_2} and Φ^{-K_2} above, we compute easily that the resulting model for $\mathcal{X}_0(S^1 \times S^2, W)^\mathcal{K}$ takes the following form:

$$\begin{array}{c}
 \mathcal{X}_0(S^1 \times S^2, W)^\mathcal{K} \simeq \begin{array}{ccc}
 & \mathbf{X}_0|\mathbf{x}_0^1 & \\
 \swarrow W & & \searrow Z \\
 \mathbf{X}_0|\mathbf{x}_0^0 & & \mathbf{X}_0|\mathbf{x}_0^2 \\
 \searrow UT^{-1}\sigma+T^{-1}\tau & & \swarrow T\sigma+UT\tau \\
 & \mathbf{X}_0|\mathbf{y}_0 &
 \end{array} \oplus \begin{array}{c}
 \mathbf{X}_1|T^0\mathbf{x}' \\
 \downarrow \sigma+\tau \\
 \mathbf{X}_1|T^0\mathbf{e}
 \end{array}
 \end{array}$$

Remark 8.1. Note that $\mathcal{X}_0(S^1 \times S^2, W)^\mathcal{K}$ is isomorphic to $\mathcal{X}_0(T_{2,3})^\mathcal{K} \oplus \mathcal{X}_0(U)^\mathcal{K}$.
