

## ON THE FANO DIMENSION OF AN ENRIQUES SURFACE

FEDERICO TUFO

ABSTRACT. We construct a family of Fano fourfolds with the derived category of coherent sheaves of a general Enriques surface as semiorthogonal component. This improves a result of Kuznetsov, lowering the Fano dimension of a general Enriques surface from six to four.

## 1. INTRODUCTION

The Fano-visitor problem is a natural, yet elusive question in algebraic geometry and derived categories. First posed by Bondal in 2011, it amounts to asking if for any smooth projective variety  $X$ , there exists a smooth Fano variety  $Y$  together with a full and faithful functor  $\mathbf{D}(X) \rightarrow \mathbf{D}(Y)$ . If the answer is positive  $X$  is called Fano-visitor, and  $Y$  is called Fano-host of  $X$ . This led, in [KKLL17], to the definition of the Fano dimension of a variety  $X$ , which is the minimal dimension of Fano-hosts of  $X$ .

Let us recap some key results on the topic. Bondal and Orlov in [BO95] proved that the derived category of a hyperelliptic curve  $X$  of genus  $g$  can be embedded into the derived category of the intersection of two quadrics in  $\mathbb{P}^{2g+1}$ . Kuznetsov in [Kuz10] proved that the derived categories of some K3 surfaces are embedded into special cubic fourfolds. Bernardara, Bolognesi, and Faenzi in [BBF16] proved that every smooth plane curve is a Fano-visitor. Segal and Thomas in [ST18] proved that a general quintic threefold is a Fano-visitor in an eleven-dimensional Fano-host. Finally, Kiem, Kim, H. Lee, and K. Lee, in [KKLL17], proved that all smooth projective complete intersections are Fano-visitors.

In [Kuz18], Kuznetsov first showed that a certain divisorial family in the moduli space of Enriques surfaces (so-called *nodal Enriques*<sup>1</sup>) can be realized as Fano-visitor for a Fano fourfold, which can be written as the blow-up of  $\mathrm{Gr}(2, 4)$  in the same Enriques surface. Then he showed that an Enriques surface general in moduli can be seen as a Fano-visitor for a six-dimensional Fano-host. In summary

- if  $S$  is a *nodal Enriques* surface, then its Fano dimension is  $\leq 4$ ;
- if  $S$  is a general Enriques surface, then its Fano dimension is  $\leq 6$ .

In our work, we improve this bound for general Enriques surfaces.

**Theorem 1.1** (Theorem 3.1, Corollary 3.3). *Let  $S$  be a general Enriques surface. Then the Fano dimension of  $S$  is 4, i.e. there exists a Fano fourfold  $Y$  with*

$$\mathbf{D}(Y) = \langle \mathbf{D}(S), E_1, \dots, E_9 \rangle$$

where  $E_1, \dots, E_9$  are exceptional bundles. The Hodge diamond of  $Y$  is diagonal, and  $K_0(Y)$  contains a 2-torsion class; in particular,  $\mathbf{D}(Y)$  does not have a full exceptional collection.

Such a Fano fourfold  $Y$  can be realized as a complete intersection of multidegrees  $(1, 2, 0), (1, 0, 2)$  in  $\mathbb{P}^2 \times \mathbb{P}^2 \times \mathbb{P}^2$ . More precisely

$$Y \cong \mathrm{Bl}_S(\mathbb{P}^2 \times \mathbb{P}^2).$$

---

<sup>1</sup>Despite the name, these Enriques surfaces are smooth.

Kuznetsov's construction and ours are deeply intertwined. We describe this relation in [Section 3](#).

Moreover, in [Proposition 2.4](#), we prove a general result that solves the Fano-visitor problem for certain smooth degeneracy loci.

**Notation.** In this paper, all varieties are defined over a number field  $\mathbb{K}$  of characteristic zero. We denote a  $\mathbb{K}$ -vector space of dimension  $n$  as  $V_n$ . The Grassmannian  $\mathrm{Gr}(k, n)$  is the variety parametrizing subspaces  $V_k \subset V_n$ . On  $\mathrm{Gr}(k, n)$ , we have the Euler sequence

$$0 \rightarrow \mathcal{U}_{\mathrm{Gr}(k, n)} \rightarrow \mathcal{O}_{\mathrm{Gr}(k, n)} \otimes V_n \rightarrow \mathcal{Q}_{\mathrm{Gr}(k, n)} \rightarrow 0,$$

where  $\mathcal{U}_{\mathrm{Gr}(k, n)}$  is the tautological bundle of rank  $k$  and  $\mathcal{Q}_{\mathrm{Gr}(k, n)}$  is the quotient bundle of rank  $n - k$ , with ample determinant.

Let  $X$  be a variety, and let  $\mathcal{E}$  be a vector bundle on  $X$  of rank  $e$ . For every integer  $k \leq e$ , we denote  $\mathrm{Gr}_X(k, \mathcal{E})$  the Grassmann bundle of  $\mathcal{E}$ , which parametrizes  $k$ -dimensional vector subspaces in the fibers of  $\mathcal{E}$ . For  $\mathrm{Gr}_X(k, \mathcal{E})$  one has the relative Euler sequence

$$0 \rightarrow \mathcal{U}_{\mathcal{E}} \rightarrow p^* \mathcal{E} \rightarrow \mathcal{Q}_{\mathcal{E}} \rightarrow 0$$

where  $p$  is the natural projection  $p: \mathrm{Gr}_X(k, \mathcal{E}) \rightarrow X$ , and  $\mathcal{U}_{\mathcal{E}}$  the relative tautological bundle for which  $p_* \mathcal{U}_{\mathcal{E}} = \mathcal{E}$ .

Let  $\mathcal{E}$  and  $\mathcal{F}$  be two vector bundles on  $X$  of rank  $e$  and  $f$  respectively. If  $\varphi: \mathcal{E} \rightarrow \mathcal{F}$  is a morphism of vector bundles, we denote with  $D_r(\varphi) \subset X$  the locus where  $\mathrm{rank}(\varphi_x) \leq r$ , which is the  $(\min(e, f) - r)$ -th degeneracy locus of  $\varphi$ . If  $\mathcal{F}$  is a globally generated vector bundle on a smooth variety  $X$ , we denote with  $\mathcal{Z}(\mathcal{F}) \subset X$  the zero locus of a general global section of  $\mathcal{F}$  in  $X$ , and we denote with  $V(\varphi) \subset X$  the zero locus of the global section  $\varphi$ .

We denote with  $\mathbf{D}(X)$  the bounded derived category of coherent sheaves on  $X$ .

## 2. THE GEOMETRIC CONSTRUCTION

**Degeneracy loci.** In order to construct our example, we first introduce some useful tools for the study of degeneracy loci of morphisms of vector bundles. Most of the results are classical, e.g., [\[Ful84, Wey03, DBFT22, BFMT21, FTT24\]](#).

**Theorem 2.1.** [\[Ful84, Theorem 14.4\]](#) *Let  $X$  be a smooth projective variety, let  $\mathcal{E}$  and  $\mathcal{F}$  vector bundles on  $X$  such that  $\mathcal{E}^\vee \otimes \mathcal{F}$  is globally generated, and let  $\varphi \in H^0(X, \mathcal{E}^\vee \otimes \mathcal{F})$  a general global section. If  $D_r(\varphi) \neq \emptyset$ , then the dimension of  $D_r(\varphi)$  is  $m_r = \dim X - (\mathrm{rk} \mathcal{E} - r)(\mathrm{rk} \mathcal{F} - r)$ .*

With the above notation, let  $p: \mathrm{Gr}_X(k, \mathcal{E}) \rightarrow X$  be the natural projection to  $X$  and assume  $k \leq \mathrm{rk} \mathcal{E}$ . By the projection formula, we have

$$p_*(p^* \mathcal{F} \otimes \mathcal{U}_{\mathcal{E}}^\vee) \cong \mathcal{F} \otimes p_*(\mathcal{U}_{\mathcal{E}}^\vee) \cong \mathcal{F} \otimes \mathcal{E}^\vee.$$

Moreover, by the Leray spectral sequence, we obtain

$$H^0(\mathrm{Gr}(k, \mathcal{E}), p^* \mathcal{F} \otimes \mathcal{U}_{\mathcal{E}}^\vee) \cong H^0(X, \mathcal{E}^\vee \otimes \mathcal{F}). \quad (1)$$

In particular, for a general global section  $\varphi \in H^0(X, \mathcal{E}^\vee \otimes \mathcal{F})$ , there exists a unique global section  $\varphi_{\mathcal{E}} \in H^0(\mathrm{Gr}(k, \mathcal{E}), p^* \mathcal{F} \otimes \mathcal{U}_{\mathcal{E}}^\vee)$  via the isomorphism (1). Notice that  $\varphi_{\mathcal{E}}$  is given by the composition  $\mathcal{U}_{\mathcal{E}} \hookrightarrow p^* \mathcal{E} \xrightarrow{p^* \varphi} p^* \mathcal{F}$ . Analogously, let  $q : \mathrm{Gr}_X(k, \mathcal{F}^\vee) \rightarrow X$  be the natural projection on  $X$ , and assume  $k \leq \mathrm{rk} \mathcal{F}$ . Then we have

$$H^0(\mathrm{Gr}(k, \mathcal{F}^\vee), q^* \mathcal{E}^\vee \otimes \mathcal{U}_{\mathcal{F}^\vee}^\vee) \cong H^0(X, \mathcal{E}^\vee \otimes \mathcal{F}). \quad (2)$$

In particular, there exists a unique  $\varphi_{\mathcal{F}^\vee} \in H^0(\mathrm{Gr}(k, \mathcal{F}^\vee), q^* \mathcal{E}^\vee \otimes \mathcal{U}_{\mathcal{F}^\vee}^\vee)$  associated to  $\varphi$ , given by the composition  $q^* \mathcal{E} \xrightarrow{q^* \varphi} q^* \mathcal{F} \twoheadrightarrow \mathcal{U}_{\mathcal{F}^\vee}^\vee$ .

Here, we introduce a useful notion for what follows.

**Definition 2.2.** Let  $X$  be a variety. A stratified Grassmann bundle on  $X$  with general fiber  $\mathrm{Gr}(k, n)$  is a pair  $(Y, p)$ , where  $Y$  is a variety and  $p$  is a surjective morphism  $p : Y \rightarrow X$  such that  $X$  admits a stratification  $X = \bigsqcup_i X_i$ , for which the morphisms  $p^{-1}(X_i) \rightarrow X_i$  are locally trivial  $\mathrm{Gr}(k, n+i)$ -bundles for all  $i$ . If  $k = 1$ , we call it a stratified projective bundle.

The next result is a combination of [Kuz16, Lemma 2.1] and classical facts, but we provide a full proof because we were unable to find it in this form elsewhere.

**Lemma 2.3.** *Let  $X$  be a smooth variety. Consider*

$$\varphi : \mathcal{E} \rightarrow \mathcal{F}$$

*a general morphism of vector bundles of  $\mathrm{rk} \mathcal{E} = e > f = \mathrm{rk} \mathcal{F}$  on  $X$  such that  $\mathcal{E}^\vee \otimes \mathcal{F}$  is globally generated. Let  $p : \mathrm{Gr}_X(k, \mathcal{E}) \rightarrow X$  be the natural projection and consider*

$$\varphi_{\mathcal{E}} \in H^0(\mathrm{Gr}_X(k, \mathcal{E}), p^* \mathcal{F} \otimes \mathcal{U}_{\mathcal{E}}^\vee),$$

*the global section of  $p^* \mathcal{F} \otimes \mathcal{U}_{\mathcal{E}}^\vee$  defined as the composition*

$$\mathcal{U}_{\mathcal{E}} \hookrightarrow p^* \mathcal{E} \xrightarrow{p^* \varphi} p^* \mathcal{F}.$$

*Assume that  $D_{f-1}(\varphi)$  is non-empty. Then the following statements hold.*

*i. If  $k = e - f$ , the variety*

$$Y_1 = V(\varphi_{\mathcal{E}}) \subset \mathrm{Gr}_X(e - f, \mathcal{E})$$

*is birational to  $X$  via the restriction of the natural projection  $p$ . Moreover, the exceptional locus of  $p|_{Y_1}$  on  $X$  is  $D_{f-1}(\varphi)$ .*

*ii. If  $k = 1$ , the variety*

$$Y_2 = V(\varphi_{\mathcal{E}}) \subset \mathbb{P}_X(\mathcal{E})$$

*is a stratified projective bundle on  $X$  with general fiber  $\mathbb{P}^{e-f-1}$ . Let  $q : \mathbb{P}_X(\mathcal{F}^\vee) \rightarrow X$  be the natural projection, and consider*

$$\varphi_{\mathcal{F}^\vee} \in H^0(\mathbb{P}_X(\mathcal{F}^\vee), q^* \mathcal{E}^\vee \otimes \mathcal{O}_{\mathcal{F}^\vee}(1)),$$

*the global section of  $q^* \mathcal{E}^\vee \otimes \mathcal{O}_{\mathcal{F}^\vee}(1)$  obtained as the composition*

$$q^* \mathcal{E} \xrightarrow{q^* \varphi} q^* \mathcal{F} \twoheadrightarrow \mathcal{O}_{\mathcal{F}^\vee}(1).$$

*Then,  $D_{f-1}(\varphi)$  is birational to*

$$Z = V(\varphi_{\mathcal{F}^\vee}) \subset \mathbb{P}_X(\mathcal{F}^\vee).$$

*iii. With the above notation, if  $k = e - f$  and  $f = e - 1$ , then  $Y_1 = Y_2$  and we call it  $Y$ . Then,*

$$Y = \mathrm{Bl}_{D_{f-1}(\varphi)} X,$$

*and  $D_{f-1}(\varphi)$  is birational to  $Z$ .*

*Proof.* Let us start by proving (i). By definition,  $\mathbb{G}\mathrm{r}_X(e-f, \mathcal{E})$  is the variety that parametrizes the pairs  $(x, V_x)$ , with  $x \in X$  and  $V_x$  a  $(e-f)$ -dimensional subspace of  $\mathcal{E}_x$ . A point  $y \in Y_1$  is a pair  $(x, V_x) \in \mathbb{G}\mathrm{r}_X(e-f, \mathcal{E})$ , such that  $\varphi_{\mathcal{E},x}(V_x) = 0$ . Notice that, by isomorphism (1), the points  $x \in X$  for which  $\varphi_{\mathcal{E},x}(V_x) = 0$  are the points in  $X$  for which  $\varphi_x(V_x) = 0$ . Thus, the fiber of  $p|_{Y_1}$  is the set of all the  $V_x \subset \ker \varphi_x$  of dimension  $e-f$  in  $\ker \varphi_x$ , which corresponds to the Grassmannian  $\mathrm{Gr}(e-f, \dim(\ker \varphi_x))$ . This implies that generically the fiber  $p|_{Y_1}^{-1}(x)$  is a point, because generically,  $\mathrm{rk} \varphi_x = f$ , hence  $\dim(\ker \varphi_x) = e-f$ . Notice that  $X$  has a stratification induced by

$$X = D_f(\varphi) \supset D_{f-1}(\varphi) \supset D_{f-2}(\varphi) \supset \dots$$

Then, over the  $X_i = D_{f-i}(\varphi) \setminus D_{f-i-1}(\varphi)$ , the map  $p|_{Y_1} : Y_1 \rightarrow X$  is a locally trivial  $\mathrm{Gr}(e-f, e-f+i)$ -bundle. Therefore, the pair  $(Y_1, p|_{Y_1})$  is a stratified Grassmann bundle with generic fiber a point on  $X$ . The dimension of the preimage of  $X_i$  is

$$\dim(X) - i(e-f+i) + i(e-f) = \dim(X) - i^2.$$

Therefore the dimension of the induced stratification on  $Y_1$  is less than  $\dim(X)$ , i.e. the dimension of the open stratum. Thus  $\dim(Y_1) \leq \dim(X)$ . Notice that  $Y_1$  is the zero locus of a global section of a vector bundle of rank  $f$  on a smooth variety  $\mathbb{G}\mathrm{r}_X(e-f, \mathcal{E})$  of dimension  $\dim(X) + f$ . It follows that  $Y_1$  is Cohen–Macaulay and irreducible. In particular,

$$p|_{Y_1} : Y_1 \rightarrow X$$

is a birational map, with exceptional locus  $D_{f-1}(\varphi)$ .

For (ii), consider the stratification

$$X = D_f(\varphi) \supset D_{f-1}(\varphi) \supset D_{f-2}(\varphi) \supset \dots$$

Then, over  $X_i = D_{f-i}(\varphi) \setminus D_{f-i-1}(\varphi)$ , the map  $p|_{Y_2} : Y_2 \rightarrow X$  is a locally trivial  $\mathbb{P}^{e-f+i-1}$ -bundle. Therefore the pair  $(Y_2, p|_{Y_2})$  is a stratified projective bundle with generic fiber  $\mathbb{P}^{e-f-1}$  on  $X$ . The dimension of the preimage of  $X_i$  is

$$\dim(X) - i(e-f+i) + (e-f+i-1) = \dim(X) + (e-f-1) - i(e-f+i-1).$$

For  $i \geq 1$ , one has  $i(e-f+i-1) > 1$ , hence the dimension of the induced stratification on  $Y_2$  is less than  $\dim(X) + (e-f+1)$ , i.e. the dimension of the open stratum. Thus,  $\dim(Y_2) \leq \dim(X) + (e-f+1)$ . On the other hand,  $Y_2$  is the zero locus of a global section of a vector bundle of rank  $f$  on the smooth variety  $\mathbb{P}_X(\mathcal{E})$  of dimension  $\dim(X) + (e-1)$ . It follows that  $Y$  is Cohen–Macaulay and irreducible.

We now study  $Z$ . Using the same argument as above, we have a stratification of  $X$  as  $X = \bigsqcup X_i$ , with  $X_i = D_{f-i}(\varphi) \setminus D_{f-i-1}(\varphi)$ . For  $x \in X_i$ , we have that  $q|_Z^{-1}(x)$  is  $\mathbb{P}(\ker \varphi_x^T)$ . In particular, if  $x \in X_0$  then the fiber is empty, while if  $x \in X_i$  for  $i \geq 1$ , the fiber is  $\mathbb{P}^{i-1}$ . Thus, the pair  $(Z, q|_Z)$  is a stratified projective bundle on  $D_{f-1}(\varphi)$ , with general fiber a point. In particular, for  $i \geq 1$ , the dimension of the preimage of  $X_i$  is

$$\dim(X) - i(e-f+1) + (i-1) = \dim(D_{f-1}(\varphi)) + (1-i)(e-f+i).$$

Hence, for  $i \geq 2$ , the dimension of every stratum of the induced stratification of  $Z$  is less than  $\dim(D_{f-1}(\varphi))$ , therefore  $Z \leq D_{f-1}(\varphi) = \dim(X) - (e-f+1)$ . On the other hand,  $Z$  is the zero locus of a global section of a vector bundle of rank  $e$  on a smooth variety  $\mathbb{P}_X(\mathcal{F}^\vee)$  of dimension  $\dim(X) + f - 1$ , it follows that  $Z$  is Cohen–Macaulay and irreducible of dimension  $\dim(X) - (e-f+1)$ . In particular,  $Z$  is birational to  $D_{f-1}(\varphi)$ .

Finally, we prove (iii). If  $f = e-1$ , we are in the hypothesis of [Kuz16, Lemma 2.1], so the first part follows. It remains to study  $Z$ . But this follows from point (ii).  $\square$

As a consequence of the previous lemma, we can prove a result which solves the Fano-visitor problem for a significant class of examples.

**Proposition 2.4.** *Let  $X$  be a smooth variety. Let  $\mathcal{E}, \mathcal{F}$  be vector bundles of ranks  $\text{rk } \mathcal{E} = e > f = \text{rk } \mathcal{F}$  such that  $\mathcal{E}^\vee \otimes \mathcal{F}$  is globally generated, and let  $\varphi : \mathcal{E} \rightarrow \mathcal{F}$  be a general morphism of vector bundles. Let  $p : \mathbb{P}_X(\mathcal{E}) \rightarrow X$  and  $q : \mathbb{P}_X(\mathcal{F}^\vee) \rightarrow X$  the natural projections, and consider*

$$\varphi_{\mathcal{E}} \in H^0(\mathbb{P}_X(\mathcal{E}), p^* \mathcal{F} \otimes \mathcal{O}_{\mathcal{E}}(1)), \quad \varphi_{\mathcal{F}^\vee} \in H^0(\mathbb{P}_X(\mathcal{F}^\vee), q^* \mathcal{E}^\vee \otimes \mathcal{O}_{\mathcal{F}^\vee}(1))$$

corresponding to  $\varphi$ . Define the varieties

$$Y = V(\varphi_{\mathcal{E}}) \subset \mathbb{P}_X(\mathcal{E}), \quad Z = V(\varphi_{\mathcal{F}^\vee}) \subset \mathbb{P}_X(\mathcal{F}^\vee).$$

Suppose the following conditions hold:

- a.  $D_{f-2}(\varphi) = \emptyset$ ;
- b.  $p^*(K_X \otimes \det \mathcal{E} \otimes \det \mathcal{F}) \otimes \mathcal{O}_{\mathcal{E}}(-e + f)$  is anti-ample;

Then  $Y$  is a Fano host for  $Z$ .

*Proof.* By [Lemma 2.3\(ii\)](#), we have that  $Y$  is a stratified projective bundle on  $X$  with generic fiber  $\mathbb{P}^{e-f-1}$ , which changes to a  $\mathbb{P}^{e-f}$  on  $D_{f-1}(\varphi)$ . By [Lemma 2.3\(ii\)](#),  $D_{f-1}(\varphi)$  is birational to  $Z$  and, since  $D_{f-2}(\varphi)$  is empty for (a), they are isomorphic.

We want to prove that there exists an embedding  $\mathbf{D}(Z) \rightarrow \mathbf{D}(Y)$ . Notice that on  $D_{f-1}(\varphi)$  the projection  $p|_Y$  is a locally trivial  $\mathbb{P}^{e-f}$ -bundle, hence

$$\dim(Z \times_X Y) = \dim(Z) + (e - f) = \dim(X) - 1.$$

Thus we can apply [\[Kuz07, Theorem 8.8\]](#), and obtain

$$\mathbf{D}(Y) = \langle \mathbf{D}(Z), p^* \mathbf{D}(X) \otimes \mathcal{O}_{\mathcal{E}}(1), \dots, p^* \mathbf{D}(X) \otimes \mathcal{O}_{\mathcal{E}}(e - f) \rangle.$$

Note that the canonical bundle of  $\mathbb{P}_X(\mathcal{E})$  is

$$K_{\mathbb{P}_X(\mathcal{E})} = p^*(K_X \otimes \det \mathcal{E}) \otimes \mathcal{O}_{\mathcal{E}}(-e),$$

with  $p : \mathbb{P}_X(\mathcal{E}) \rightarrow X$  the natural projection. By the adjunction formula and condition (b), the anticanonical bundle of  $Y$  is the restriction of an ample line bundle, hence is ample. Therefore,  $Y$  is a Fano variety.  $\square$

**Remark 2.5.** If  $X$  is a smooth Fano variety with Picard rank one, for example a Grassmannian, then the condition (b) in [Proposition 2.4](#) becomes a numerical condition. In fact, let  $\iota_X$  be the index of  $X$ , and let  $\det \mathcal{E} \cong \mathcal{O}_X(\alpha)$ ,  $\det \mathcal{F} \cong \mathcal{O}_X(\beta)$ . Then the condition (b) can be rewritten as:  $\iota_X - \alpha - \beta > 0$  and  $f < e$ .

We obtain in this way a new set of varieties for which the Fano-visitor problem has a positive answer. As an application, we show an improvement to the Fano dimension of a general Enriques surface.

### 3. A GENERAL ENRIQUES SURFACE AND ITS HOST

In this final section, we discuss two Fano-hosts for a general Enriques surface: the first one is six-dimensional and described by Kuznetsov in [\[Kuz18\]](#); the second one is four-dimensional, and it is the main result of this paper.

We fix the following notation: let  $V_3$ ,  $V'_3$ ,  $W_3$  be 3-dimensional vector spaces,  $X = \mathbb{P}(V_3) \times \mathbb{P}(V'_3)$ ,  $\mathcal{F} = \mathcal{O}_X(2, 0) \oplus \mathcal{O}_X(0, 2)$ ,  $\mathcal{E} = \mathcal{O}_X \otimes W_3$ , and  $q : \mathbb{P}_X(\mathcal{F}^\vee) \rightarrow X$  the natural projection to  $X$ .

Recall from [OS20, Lemma 2.1] that a general Enriques surface can be described as the first degeneracy loci  $D_1(\varphi)$  of a general morphism:

$$\varphi : \mathcal{E} \rightarrow \mathcal{F}.$$

By isomorphism (2)

$$H^0(X, \mathcal{E}^\vee \otimes \mathcal{F}) \cong H^0(\mathbb{P}_X(\mathcal{F}^\vee), q^* \mathcal{E}^\vee \otimes \mathcal{O}_{\mathcal{F}^\vee}(1)),$$

Denote with  $\varphi_{\mathcal{F}^\vee}$  the image of  $\varphi$  via the isomorphism (2).

Hence, we can consider the zero locus  $S = V(\varphi_{\mathcal{F}^\vee}) \subset \mathbb{P}_X(\mathcal{F}^\vee)$ , which can be written as

$$S = \mathcal{Z}(q^* \mathcal{E}^\vee \otimes \mathcal{O}_{\mathcal{F}^\vee}(1)) \subset \mathbb{P}_X(\mathcal{F}^\vee)$$

the Enriques surface considered in [Kuz18, Lemma 3]. Notice that  $q^* \mathcal{E}^\vee \otimes \mathcal{O}_{\mathcal{F}^\vee}(1) = \mathcal{O}_{\mathcal{F}^\vee}(1)^{\oplus 3}$ , and varying the three-dimensional subspace of global sections of  $\mathcal{O}_{\mathcal{F}^\vee}(1)$ , one obtains the general Enriques surface. We will show in [Theorem 3.1](#) that  $S$  and  $D_1(\varphi)$  are in fact isomorphic.

**Six-dimensional Fano-host.** In [Kuz18], in order to produce a six-dimensional Fano-host for  $S$ , Kuznetsov considered the product  $\mathbb{P}_X(\mathcal{F}^\vee) \times \mathbb{P}(W_3)$ . The key observation is the isomorphism given by the Künneth formula

$$H^0(\mathbb{P}_X(\mathcal{F}^\vee), q^* \mathcal{E}^\vee \otimes \mathcal{O}_{\mathcal{F}^\vee}(1)) \cong H^0(\mathbb{P}_X(\mathcal{F}^\vee) \times \mathbb{P}(W_3), \mathcal{O}_{\mathcal{F}^\vee}(1) \boxtimes \mathcal{O}_{\mathbb{P}(W_3)}(1)). \quad (3)$$

Hence, the same section  $\varphi$  from the previous paragraph is associated to a unique general global section  $\tilde{\varphi}$  of  $H^0(\mathbb{P}_X(\mathcal{F}^\vee) \times \mathbb{P}(W_3), \mathcal{O}_{\mathcal{F}^\vee}(1) \boxtimes \mathcal{O}_{\mathbb{P}(W_3)}(1))$ . We can then consider its zero locus  $V(\tilde{\varphi}) = T \subset \mathbb{P}_X(\mathcal{F}^\vee) \times \mathbb{P}(W_3)$ , i.e.

$$T = \mathcal{Z}(\mathcal{O}_{\mathcal{F}^\vee}(1) \boxtimes \mathcal{O}_{\mathbb{P}(W_3)}(1)) \subset \mathbb{P}_X(\mathcal{F}^\vee) \times \mathbb{P}(W_3).$$

In [Kuz18, Theorem 4] is proved that  $T$  is a Fano sixfold, described as a stratified projective bundle bundle on  $\mathbb{P}_X(\mathcal{F}^\vee)$ , with general fiber a  $\mathbb{P}^1$  which jumps to a  $\mathbb{P}^2$ -bundle over  $S$ . From this, it follows that

$$\mathbf{D}(T) = \langle \mathbf{D}(S), \mathbf{D}(\mathbb{P}_X(\mathcal{F}^\vee)), \mathbf{D}(\mathbb{P}_X(\mathcal{F}^\vee)) \rangle.$$

**Four-dimensional Fano-host.** The key idea behind this paper is to consider another variety  $Y$  which is defined by the very same  $\varphi$ , and to relate it with  $S$ . In fact, as in (3), one gets another canonical isomorphism

$$H^0(\mathbb{P}_X(\mathcal{F}^\vee) \times \mathbb{P}(W_3), \mathcal{O}_{\mathcal{F}^\vee}(1) \boxtimes \mathcal{O}_{\mathbb{P}(W_3)}(1)) \cong H^0(\mathbb{P}(W_3) \times X, \mathcal{O}_{\mathbb{P}(W_3)}(1) \boxtimes \mathcal{F}). \quad (4)$$

Denote with  $\hat{\varphi}$  the unique global section of  $\mathcal{O}_{\mathbb{P}(W_3)}(1) \boxtimes \mathcal{F}$  associated to  $\tilde{\varphi}$  via (4). Therefore, the zero locus  $V(\hat{\varphi}) = Y \subset \mathbb{P}(W_3) \times X$  defines a variety

$$Y = \mathcal{Z}(\mathcal{O}_{\mathbb{P}(W_3)}(1) \boxtimes \mathcal{F}) \subset \mathbb{P}(W_3) \times X,$$

which can be rewritten as

$$Y = \mathcal{Z}(\mathcal{O}(1, 0, 2) \oplus \mathcal{O}(1, 2, 0)) \subset \mathbb{P}(W_3) \times \mathbb{P}(V_3) \times \mathbb{P}(V'_3).$$

In the following, we prove that  $X$  and  $Y$  are birational, and how  $Y$  can be seen as a Fano-host for  $S$ .

**Theorem 3.1.** *The variety*

$$Y = \mathcal{Z}(\mathcal{O}(1, 0, 2) \oplus \mathcal{O}(1, 2, 0)) \subset \mathbb{P}(W_3) \times \mathbb{P}(V_3) \times \mathbb{P}(V'_3)$$

*is a Fano fourfold. Moreover,  $Y \cong \text{Bl}_S(\mathbb{P}(V_3) \times \mathbb{P}(V'_3))$ , with  $S$  a general Enriques surface.*

*Proof.* In this proof, in agreement with the above notation, we set  $X = \mathbb{P}(V_3) \times \mathbb{P}(V'_3)$ ,  $\mathcal{E} = \mathcal{O}_X \otimes W_3$ ,  $\mathcal{F} = \mathcal{O}_X(2, 0) \oplus \mathcal{O}_X(0, 2)$ .

As in the previous discussion, we start from a general morphism of vector bundles on  $X$ ,  $\varphi : \mathcal{E} \rightarrow \mathcal{F}$ . From the isomorphism in (2), denote  $\varphi_{\mathcal{F}^\vee}$  the global section of  $q^*\mathcal{E} \otimes \mathcal{O}_{\mathcal{F}^\vee}(1)$  associated to  $\varphi$ .

$$\varphi_{\mathcal{F}^\vee} \in H^0(\mathbb{P}_X(\mathcal{F}^\vee), q^*\mathcal{E}^\vee \otimes \mathcal{O}_{\mathcal{F}^\vee}(1)).$$

By [Theorem 2.1](#),  $D_1(\varphi) \subset X$  is a smooth surface, because  $D_0(\varphi)$  is empty. By [Lemma 2.3](#)(iii)  $D_1(\varphi)$  is birational to

$$S = V(\varphi_{\mathcal{F}^\vee}) \subset \mathbb{P}_X(\mathcal{F}^\vee).$$

$S$  is the Enriques surface  $S$  described in [[Kuz18](#), Lemma 3]. Notice that  $D_0(\varphi)$  is empty, thus we conclude that  $D_1(\varphi) \cong S$ .

We now turn our attention to the variety  $Y$ . The latter is defined as the zero locus of a section of a vector bundle of rank 2 in  $\mathbb{P}^2 \times \mathbb{P}^2 \times \mathbb{P}^2$ , thus  $Y$  is four-dimensional. By the adjunction formula,

$$K_Y = K_{\mathbb{P}^2 \times \mathbb{P}^2 \times \mathbb{P}^2} \otimes \mathcal{O}(1, 2, 0) \otimes \mathcal{O}(1, 0, 2)|_Y = \mathcal{O}_{\mathbb{P}^2 \times \mathbb{P}^2 \times \mathbb{P}^2}(-1, -1, -1)|_Y.$$

Hence,  $Y$  is Fano.

Notice that since  $\mathcal{E} = W_3 \otimes \mathcal{O}_X$ , then  $\mathbb{P}(W_3) \times X = \mathbb{P}_X(\mathcal{E})$ . Thus, as before, if  $p : \mathbb{P}_X(\mathcal{E}) \rightarrow X$  is the natural projection, then  $Y$  can be rewritten as

$$Y = V(\varphi_{\mathcal{E}}) \subset \mathbb{P}_X(\mathcal{E}),$$

where  $\varphi_{\mathcal{E}}$  is the global section of  $p^*\mathcal{F} \otimes \mathcal{O}_{\mathcal{E}}(1)$  associated to  $\varphi$  via the isomorphism (1). Therefore, we are in the setting of [Lemma 2.3](#). By [Lemma 2.3](#)(i),  $Y$  is birational to  $X$ . In particular, since  $f = e - 1 = 2$ , and since we have already shown that  $D_1(\varphi) \cong S$ , by [Lemma 2.3](#)(iii) we have the isomorphism

$$Y \cong \text{Bl}_S(\mathbb{P}^2 \times \mathbb{P}^2).$$

□

We are now in the position to describe the numerical invariants and the categorical properties of  $Y$ .

Since  $Y$  is a complete intersection, its invariants can be quickly computed using standard exact sequences and the Riemann-Roch theorem.

**Corollary 3.2.** *The variety  $Y$  has the following invariants:*

$$e(Y) = 21, \quad h^0(-K_Y) = 27, \quad (-K_Y)^4 = 102.$$

The half-lower Hodge diamond of  $Y$  is

$$\begin{array}{cccccc} 0 & 0 & 13 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 3 & 0 & 0 & \\ 0 & 0 & & & \\ & & 1 & & \end{array}$$

Moreover, if  $\Lambda \subset H^2(S, \mathbb{Z})$  is the rank ten lattice associated to the Enriques surface  $S$ , the integral cohomology of  $Y$  is:

$$H^k(Y, \mathbb{Z}) = \begin{cases} \mathbb{Z} & \text{if } k = 0, 8 \\ \mathbb{Z}^{\oplus 3} & \text{if } k = 2, 6 \\ \mathbb{Z}^{\oplus 3} \oplus \Lambda \oplus \mathbb{Z}/2\mathbb{Z} & \text{if } k = 4 \\ 0 & \text{otherwise} \end{cases}$$

**Corollary 3.3.** *The variety  $Y$  is a fourfold with a semiorthogonal decomposition*

$$\mathbf{D}(Y) = \langle \mathbf{D}(S), E_1, \dots, E_9 \rangle$$

where  $E_1, \dots, E_9$  are exceptional bundles. The Hodge diamond of  $Y$  is diagonal, but  $K^0(Y)$  contains a 2-torsion class; in particular,  $\mathbf{D}(Y)$  does not have a full exceptional collection.

*Proof.* The semiorthogonal decomposition is given by Orlov's blow-up formula and the fact that  $\mathbf{D}(\mathbb{P}^2 \times \mathbb{P}^2)$  is generated by an exceptional collection of length nine.

The Grothendieck group is additive with respect to semiorthogonal decompositions, hence

$$K_0(Y) = K_0(S) \oplus \mathbb{Z}^{\oplus 9}.$$

Notice that the 2-torsion in  $S$  induces a 2-torsion in  $Y$ , hence, by [Kuz18, Lemma 1],  $\mathbf{D}(Y)$  does not have a full exceptional collection.  $\square$

This yields a four-dimensional variety as a solution to the Fano-visitor problem for Enriques surfaces general in moduli.

With Corollary 3.3 we proved that the Fano dimension of  $S$  is at most 4. Observe that neither  $\mathbb{P}^1$  nor a del Pezzo surface can be a Fano-host for  $S$ . Therefore, if one shows that no Fano threefolds can be a Fano host for  $S$ , it follows that the Fano dimension of a general Enriques surface is 4.

Assume by contradiction that  $Y$  is a three-dimensional Fano host for  $S$ . Then we obtain the following inequality on the dimensions of Hochschild homology:

$$12 = \dim(\mathrm{HH}_0(S)) \leq (\dim \mathrm{HH}_0(Y)).$$

If  $\rho(Y)$  denotes the Picard rank of  $Y$ , we have

$$\dim \mathrm{HH}_0(Y) = 2 + \rho(Y),$$

and hence  $\rho(Y) \geq 5$ . By classification of Fano threefolds, there are only eight families of Fano threefolds with Picard rank  $\geq 5$ , and all of them admit a full exceptional collection. This implies that  $K_0(Y)$  is torsion-free, which contradicts the assumption that  $K_0(S) \subset K_0(Y)$ .
